<td>[str, num]</td>
<td>['equal', 'auto'] or a number. If a number the ratio of x-unit/y-unit in screen-space. Also see set_aspect().</td>
</tr>
</tbody>
</table>

Examples:

- `examples/pylab_examples/axes_demo.py` places custom axes.
- `examples/pylab_examples/shared_axis_demo.py` uses `sharex` and `sharey`.

matplotlib.pyplot.axhline(y=0, xmin=0, xmax=1, hold=None, **kwargs)

Add a horizontal line across the axis.

**Parameters**

- **y** : scalar, optional, default: 0
  
  y position in data coordinates of the horizontal line.

- **xmin** : scalar, optional, default: 0
  
  Should be between 0 and 1, 0 being the far left of the plot, 1 the far right of the plot.

- **xmax** : scalar, optional, default: 1
  
  Should be between 0 and 1, 0 being the far left of the plot, 1 the far right of the plot.

**Returns** Line2D

**See also:**

- `axhspan` for example plot and source code

**Notes**

kwargs are passed to Line2D and can be used to control the line properties.
Examples

- draw a thick red hline at ‘y’ = 0 that spans the xrange:

  ```
  >>> axhline(linewidth=4, color='r')
  ```

- draw a default hline at ‘y’ = 1 that spans the xrange:

  ```
  >>> axhline(y=1)
  ```

- draw a default hline at ‘y’ = .5 that spans the middle half of the xrange:

  ```
  >>> axhline(y=.5, xmin=0.25, xmax=0.75)
  ```

Valid kwargs are *Line2D* properties, with the exception of ‘transform’:

```python
closer_test.
```

**matplotlib.pyplot.axhspan**(ymin, ymax, xmin=0, xmax=1, hold=None, **kwargs)

Add a horizontal span (rectangle) across the axis.

Draw a horizontal span (rectangle) from ymin to ymax. With the default values of xmin = 0 and xmax = 1, this always spans the xrange, regardless of the xlim settings, even if you change them, e.g., with the `set_xlim()` command. That is, the horizontal extent is in axes coords: 0=left, 0.5=middle, 1.0=right but the y location is in data coordinates.

**Parameters**

`ymin` : float

Lower limit of the horizontal span in data units.

`ymax` : float

Upper limit of the horizontal span in data units.

`xmin` : float, optional, default: 0

Lower limit of the vertical span in axes (relative 0-1) units.

`xmax` : float, optional, default: 1

Upper limit of the vertical span in axes (relative 0-1) units.

**Returns**

`Polygon` : `Polygon`

**Other Parameters**

`kwargs` : `Polygon` properties.

**See also:**

`axvspan` Add a vertical span (rectangle) across the axes.
Examples

```
matplotlib.pyplot.axis(*v, **kwargs)

Convenience method to get or set axis properties.

Calling with no arguments:

```python
>>> axis()
```
returns the current axes limits [xmin, xmax, ymin, ymax]:

```python
>>> axis(v)
```
sets the min and max of the x and y axes, with v = [xmin, xmax, ymin, ymax]:

```python
>>> axis('off')
```
turns off the axis lines and labels:

```python
>>> axis('equal')
```
changes limits of x or y axis so that equal increments of x and y have the same length; a circle is circular.
achieves the same result by changing the dimensions of the plot box instead of the axis data limits:

```python
>>> axis('scaled')
```

changes $x$ and $y$ axis limits such that all data is shown. If all data is already shown, it will move it to the center of the figure without modifying $(x_{\text{max}} - x_{\text{min}})$ or $(y_{\text{max}} - y_{\text{min}})$. Note this is slightly different than in MATLAB:

```python
>>> axis('tight')
```

is ‘scaled’ with the axis limits equal to the data limits:

```python
>>> axis('image')
```

are deprecated. They restore default behavior; axis limits are automatically scaled to make the data fit comfortably within the plot box.

```python
>>> axis('square')
```

changes the limit ranges $(x_{\text{max}}-x_{\text{min}})$ and $(y_{\text{max}}-y_{\text{min}})$ of the $x$ and $y$ axes to be the same, and have the same scaling, resulting in a square plot.

The $x_{\text{min}}, x_{\text{max}}, y_{\text{min}}, y_{\text{max}}$ tuple is returned

See also:

- `xlim()`, `ylim()` For setting the x- and y-limits individually.

```python
matplotlib.pyplot.axvline(x=0, ymin=0, ymax=1, hold=None, **kwargs)
```

Add a vertical line across the axes.

**Parameters**

- $x$: scalar, optional, default: 0
  
  x position in data coordinates of the vertical line.

- $y_{\text{min}}$: scalar, optional, default: 0
  
  Should be between 0 and 1, 0 being the bottom of the plot, 1 the top of the plot.

- $y_{\text{max}}$: scalar, optional, default: 1
  
  Should be between 0 and 1, 0 being the bottom of the plot, 1 the top of the plot.
Returns `Line2D`

See also:

`axhspan` for example plot and source code

Examples

- draw a thick red vline at $x = 0$ that spans the yrange:
  
  ```python
  >>> axvline(linewidth=4, color='r')
  ```

- draw a default vline at $x = 1$ that spans the yrange:
  
  ```python
  >>> axvline(x=1)
  ```

- draw a default vline at $x = .5$ that spans the middle half of the yrange:
  
  ```python
  >>> axvline(x=.5, ymin=0.25, ymax=0.75)
  ```

Valid kwargs are `Line2D` properties, with the exception of ‘transform’:

**matplotlib.pyplot.axvspan** (*xmin, xmax, ymin=0, ymax=1, hold=None, **kwargs*)

Add a vertical span (rectangle) across the axes.

Draw a vertical span (rectangle) from *xmin* to *xmax*. With the default values of *ymin* = 0 and *ymax* = 1. This always spans the yrange, regardless of the ylim settings, even if you change them, e.g., with the **set_ylim()** command. That is, the vertical extent is in axes coords: 0=bottom, 0.5=middle, 1.0=top but the y location is in data coordinates.

**Parameters**

- **xmin** : scalar
  Number indicating the first X-axis coordinate of the vertical span rectangle in data units.

- **xmax** : scalar
  Number indicating the second X-axis coordinate of the vertical span rectangle in data units.

- **ymin** : scalar, optional
  Number indicating the first Y-axis coordinate of the vertical span rectangle in relative Y-axis units (0-1). Default to 0.

- **ymax** : scalar, optional
  Number indicating the second Y-axis coordinate of the vertical span rectangle in relative Y-axis units (0-1). Default to 1.

**Returns**

- **rectangle** : matplotlib.patches.Polygon
Vertical span (rectangle) from (xmin, ymin) to (xmax, ymax).

Other Parameters **kwargs

Optional parameters are properties of the class matplotlib.patches.Polygon.

See also:

axhspan

Examples

Draw a vertical, green, translucent rectangle from x = 1.25 to x = 1.55 that spans the yrange of the axes.

```python
>>> axvspan(1.25, 1.55, facecolor='g', alpha=0.5)
```

```python
matplotlib.pyplot.bar(left, height, width=0.8, bottom=None, hold=None, data=None, **kwargs)
```

Make a bar plot.

Make a bar plot with rectangles bounded by:

```
left, left + width, bottom, bottom + height
```

( left, right, bottom and top edges)

Parameters left : sequence of scalars
    the x coordinates of the left sides of the bars

height : sequence of scalars
    the heights of the bars

width : scalar or array-like, optional
    the width(s) of the bars default: 0.8

bottom : scalar or array-like, optional
    the y coordinate(s) of the bars default: None

color : scalar or array-like, optional
    the colors of the bar faces

decorcolor : scalar or array-like, optional
    the colors of the bar edges

linewidth : scalar or array-like, optional
    width of bar edge(s). If None, use default linewidth; If 0, don’t draw edges. default: None

tick_label : string or array-like, optional
    the tick labels of the bars default: None
**xerr**: scalar or array-like, optional

   if not None, will be used to generate errorbar(s) on the bar chart default: None

**yerr**: scalar or array-like, optional

   if not None, will be used to generate errorbar(s) on the bar chart default: None

**ecolor**: scalar or array-like, optional

   specifies the color of errorbar(s) default: None

**capsize**: scalar, optional

   determines the length in points of the error bar caps default: None, which will take the value from the `errorbar.capsize rcParam`.

**error_kw**: dict, optional

   dictionary of kwargs to be passed to errorbar method. `ecolor` and `capsize` may be specified here rather than as independent kwargs.

**align**: {'center', 'edge'}, optional

   If 'edge', aligns bars by their left edges (for vertical bars) and by their bottom edges (for horizontal bars). If 'center', interpret the `left` argument as the coordinates of the centers of the bars. To align on the align bars on the right edge pass a negative `width`.

**orientation**: {'vertical', 'horizontal'}, optional

   The orientation of the bars.

**log**: boolean, optional

   If true, sets the axis to be log scale. default: False

**Returns**

   **bars**: matplotlib.container.BarContainer

   Container with all of the bars + errorbars

**See also:**

   `barh` Plot a horizontal bar plot.

**Notes**

   The optional arguments `color`, `edgecolor`, `linewidth`, `xerr`, and `yerr` can be either scalars or sequences of length equal to the number of bars. This enables you to use bar as the basis for stacked bar charts, or candlestick plots. Detail: `xerr` and `yerr` are passed directly to `errorbar()`, so they can also have shape 2xN for independent specification of lower and upper errors.

**Examples**

**Example:** A stacked bar chart.
Scores by group and gender

Note: In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

```
matplotlib.pyplot.barbs(*args, **kw)
```

Plot a 2-D field of barbs.

Call signatures:

```
barb(U, V, **kw)
barb(U, V, C, **kw)
barb(X, Y, U, V, **kw)
barb(X, Y, U, V, C, **kw)
```

Arguments:

- `X, Y`: The x and y coordinates of the barb locations (default is head of barb; see `pivot` kwarg)
- `U, V`: Give the x and y components of the barb shaft
- `C`: An optional array used to map colors to the barbs
All arguments may be 1-D or 2-D arrays or sequences. If $X$ and $Y$ are absent, they will be generated as a uniform grid. If $U$ and $V$ are 2-D arrays but $X$ and $Y$ are 1-D, and if \text{len}(X)$ and \text{len}(Y) match the column and row dimensions of $U$, then $X$ and $Y$ will be expanded with \texttt{numpy.meshgrid}().

$U$, $V$, $C$ may be masked arrays, but masked $X$, $Y$ are not supported at present.

Keyword arguments:

\textbf{length:} Length of the barb in points; the other parts of the barb are scaled against this. Default is 9

\textbf{pivot:} \{ ‘tip’ | ‘middle’ \} The part of the arrow that is at the grid point; the arrow rotates about this point, hence the name \texttt{pivot}. Default is ‘tip’

\textbf{barbcolor:} \{ \texttt{color} | \texttt{color sequence} \} Specifies the color all parts of the barb except any flags. This parameter is analogous to the \texttt{edgecolor} parameter for polygons, which can be used instead. However this parameter will override \texttt{facecolor}.

\textbf{flagcolor:} \{ \texttt{color} | \texttt{color sequence} \} Specifies the color of any flags on the barb. This parameter is analogous to the \texttt{facecolor} parameter for polygons, which can be used instead. However this parameter will override \texttt{facecolor}. If this is not set (and $C$ has not either) then \texttt{flagcolor} will be set to match \texttt{barbcolor} so that the barb has a uniform color. If $C$ has been set, \texttt{flagcolor} has no effect.

\textbf{sizes:} A dictionary of coefficients specifying the ratio of a given feature to the length of the barb. Only those values one wishes to override need to be included. These features include:

- ‘spacing’ - space between features (flags, full/half barbs)
- ‘height’ - height (distance from shaft to top) of a flag or full barb
- ‘width’ - width of a flag, twice the width of a full barb
- ‘emptybarb’ - radius of the circle used for low magnitudes

\textbf{fill_empty:} A flag on whether the empty barbs (circles) that are drawn should be filled with the flag color. If they are not filled, they will be drawn such that no color is applied to the center. Default is False

\textbf{rounding:} A flag to indicate whether the vector magnitude should be rounded when allocating barb components. If True, the magnitude is rounded to the nearest multiple of the half-barb increment. If False, the magnitude is simply truncated to the next lowest multiple. Default is True

\textbf{barb_increments:} A dictionary of increments specifying values to associate with different parts of the barb. Only those values one wishes to override need to be included.

- ‘half’ - half barbs (Default is 5)
- ‘full’ - full barbs (Default is 10)
- ‘flag’ - flags (default is 50)

\textbf{flip_barb:} Either a single boolean flag or an array of booleans. Single boolean indicates whether the lines and flags should point opposite to normal for all barbs. An array (which should be the same size as the other data arrays) indicates whether to flip for
each individual barb. Normal behavior is for the barbs and lines to point right (comes from wind barbs having these features point towards low pressure in the Northern Hemisphere.) Default is False

Barbs are traditionally used in meteorology as a way to plot the speed and direction of wind observations, but can technically be used to plot any two dimensional vector quantity. As opposed to arrows, which give vector magnitude by the length of the arrow, the barbs give more quantitative information about the vector magnitude by putting slanted lines or a triangle for various increments in magnitude, as show schematically below:

```
: /\ 
:\/ 
:\/ 
:\/ 
:-----------------------------
```

The largest increment is given by a triangle (or “flag”). After those come full lines (barbs). The smallest increment is a half line. There is only, of course, ever at most 1 half line. If the magnitude is small and only needs a single half-line and no full lines or triangles, the half-line is offset from the end of the barb so that it can be easily distinguished from barbs with a single full line. The magnitude for the barb shown above would nominally be 65, using the standard increments of 50, 10, and 5.

Linewidths and edgecolors can be used to customize the barb. Additional *PolyCollection* keyword arguments:

Example:

![Example Diagram](image-url)
Matplotlib, Release 2.0.0

Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All positional and all keyword arguments.

matplotlib.pyplot.barh(bottom, width, height=0.8, left=None, hold=None, **kwargs)

Make a horizontal bar plot.

Make a horizontal bar plot with rectangles bounded by:

left, left + width, bottom, bottom + height (left, right, bottom and top edges)

bottom, width, height, and left can be either scalars or sequences

Parameters:
bottom : scalar or array-like
    the y coordinate(s) of the bars
width : scalar or array-like
    the width(s) of the bars
height : sequence of scalars, optional, default: 0.8
    the heights of the bars
left : sequence of scalars
the x coordinates of the left sides of the bars

**Returns** `matplotlib.patches.Rectangle` instances.

**Other Parameters**

- **color**: scalar or array-like, optional
  the colors of the bars

- **edgecolor**: scalar or array-like, optional
  the colors of the bar edges

- **linewidth**: scalar or array-like, optional, default: None
  width of bar edge(s). If None, use default linewidth; If 0, don’t draw edges.

- **tick_label**: string or array-like, optional, default: None
  the tick labels of the bars

- **xerr**: scalar or array-like, optional, default: None
  if not None, will be used to generate errorbar(s) on the bar chart

- **yerr**: scalar or array-like, optional, default: None
  if not None, will be used to generate errorbar(s) on the bar chart

- **ecolor**: scalar or array-like, optional, default: None
  specifies the color of errorbar(s)

- **capsize**: scalar, optional
  determines the length in points of the error bar caps default: None, which will take the value from the `errorbar.capsize rcParam`.

- **error_kw**: dictionary of kwargs to be passed to errorbar method. ecolor and capsize may be specified here rather than as independent kwags.

- **align**: {'center', 'edge'}, optional
  If ‘edge’, aligns bars by their left edges (for vertical bars) and by their bottom edges (for horizontal bars). If ‘center’, interpret the bottom argument as the coordinates of the centers of the bars. To align on the align bars on the top edge pass a negative ‘height’.

- **log**: boolean, optional, default: False
  If true, sets the axis to be log scale

**See also**:

- **bar**: Plot a vertical bar plot.
Notes

The optional arguments `color`, `edgecolor`, `linewidth`, `xerr`, and `yerr` can be either scalars or sequences of length equal to the number of bars. This enables you to use `bar` as the basis for stacked bar charts, or candlestick plots. Detail: `xerr` and `yerr` are passed directly to `errorbar()`, so they can also have shape 2xN for independent specification of lower and upper errors.

Other optional kwargs:

`matplotlib.pyplot.bone()`

set the default colormap to bone and apply to current image if any. See `help(colormaps)` for more information
matplotlib.pyplot.box(on=None)

Turn the axes box on or off. on may be a boolean or a string, ‘on’ or ‘off’.

If on is None, toggle state.

matplotlib.pyplot.boxplot(x, notch=None, sym=None, vert=None, whis=None, positions=None, widths=None, patch_artist=None, bootstrap=None, usermedians=None, conf_intervals=None, medianline=None, showmeans=None, showcaps=None, showbox=None, showfliers=None, boxprops=None, labels=None, flierprops=None, medianprops=None, meanprops=None, capprops=None, whiskerprops=None, manage_xticks=True, autorange=False, zorder=None, hold=None, data=None)

Make a box and whisker plot.

Make a box and whisker plot for each column of x or each vector in sequence x. The box extends from the lower to upper quartile values of the data, with a line at the median. The whiskers extend from the box to show the range of the data. Flier points are those past the end of the whiskers.

**Parameters**

x : Array or a sequence of vectors.

The input data.

notch : bool, optional (False)

If True, will produce a notched box plot. Otherwise, a rectangular boxplot is produced. The notches represent the confidence interval (CI) around the median. See the entry for the bootstrap parameter for information regarding how the locations of the notches are computed.

**Note:** In cases where the values of the CI are less than the lower quartile or greater than the upper quartile, the notches will extend beyond the box, giving it a distinctive “flipped” appearance. This is expected behavior and consistent with other statistical visualization packages.

sym : str, optional

The default symbol for flier points. Enter an empty string ("") if you don’t want to show fliers. If None, then the fliers default to ‘b+’ If you want more control use the flierprops kwarg.

vert : bool, optional (True)

If True (default), makes the boxes vertical. If False, everything is drawn horizontally.

whis : float, sequence, or string (default = 1.5)

As a float, determines the reach of the whiskers past the first and third quartiles (e.g., Q3 + whis*IQR, IQR = interquartile range, Q3-Q1). Beyond the whiskers, data are considered outliers and are plotted as individual points. Set this to an unreasonably high value to force the whiskers to show the min and max values. Alternatively, set this to an ascending sequence of percentile
(e.g., [5, 95]) to set the whiskers at specific percentiles of the data. Finally, whis can be the string 'range' to force the whiskers to the min and max of the data.

**bootstrap** : int, optional

Specifies whether to bootstrap the confidence intervals around the median for notched boxplots. If bootstrap is None, no bootstrapping is performed, and notches are calculated using a Gaussian-based asymptotic approximation (see McGill, R., Tukey, J.W., and Larsen, W.A., 1978, and Kendall and Stuart, 1967). Otherwise, bootstrap specifies the number of times to bootstrap the median to determine its 95% confidence intervals. Values between 1000 and 10000 are recommended.

**usermedians** : array-like, optional

An array or sequence whose first dimension (or length) is compatible with x. This overrides the medians computed by matplotlib for each element of usermedians that is not None. When an element of usermedians is None, the median will be computed by matplotlib as normal.

**conf_intervals** : array-like, optional

Array or sequence whose first dimension (or length) is compatible with x and whose second dimension is 2. When the an element of conf_intervals is not None, the notch locations computed by matplotlib are overridden (provided notch is True). When an element of conf_intervals is None, the notches are computed by the method specified by the other kwargs (e.g., bootstrap).

**positions** : array-like, optional

Sets the positions of the boxes. The ticks and limits are automatically set to match the positions. Defaults to range(1, N+1) where N is the number of boxes to be drawn.

**widths** : scalar or array-like

Sets the width of each box either with a scalar or a sequence. The default is 0.5, or 0.15*(distance between extreme positions), if that is smaller.

**patch_artist** : bool, optional (False)

If False produces boxes with the Line2D artist. Otherwise, boxes and drawn with Patch artists.

**labels** : sequence, optional

Labels for each dataset. Length must be compatible with dimensions of x.

**manage_xticks** : bool, optional (True)

If the function should adjust the xlim and xtick locations.

**autorange** : bool, optional (False)
When True and the data are distributed such that the 25th and 75th percentiles are equal, whis is set to 'range' such that the whisker ends are at the minimum and maximum of the data.

**meanline**: bool, optional (False)

If True (and showmeans is True), will try to render the mean as a line spanning the full width of the box according to meanprops (see below). Not recommended if shownotches is also True. Otherwise, means will be shown as points.

**zorder**: scalar, optional (None)

Sets the zorder of the boxplot.

**Returns**

result : dict

A dictionary mapping each component of the boxplot to a list of the matplotlib.pyplot.Bbox instances created. That dictionary has the following keys (assuming vertical boxplots):

- **boxes**: the main body of the boxplot showing the quartiles and the median’s confidence intervals if enabled.
- **medians**: horizontal lines at the median of each box.
- **whiskers**: the vertical lines extending to the most extreme, non-outlier data points.
- **caps**: the horizontal lines at the ends of the whiskers.
- **fliers**: points representing data that extend beyond the whiskers (fliers).
- **means**: points or lines representing the means.

**Other Parameters**

**showcaps**: bool, optional (True)

Show the caps on the ends of whiskers.

**showbox**: bool, optional (True)

Show the central box.

**showfliers**: bool, optional (True)

Show the outliers beyond the caps.

**showmeans**: bool, optional (False)

Show the arithmetic means.

**capprops**: dict, optional (None)

Specifies the style of the caps.

**boxprops**: dict, optional (None)

Specifies the style of the box.

**whiskerprops**: dict, optional (None)
Specifies the style of the whiskers.

**flierprops**: dict, optional (None)

Specifies the style of the fliers.

**medianprops**: dict, optional (None)

Specifies the style of the median.

**meanprops**: dict, optional (None)

Specifies the style of the mean.

**Examples**

![Boxplot Examples](image-url)
I never said they'd be pretty

Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All positional and all keyword arguments.

matplotlib.pyplot.broken_barh((xranges, yrange, hold=None, data=None, **kwargs))

Plot horizontal bars.

A collection of horizontal bars spanning yrange with a sequence of xranges.

Required arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xranges</td>
<td>sequence of (xmin, xwidth)</td>
</tr>
<tr>
<td>yrange</td>
<td>sequence of (ymin, ywidth)</td>
</tr>
</tbody>
</table>
kwargs are `matplotlib.collections.BrokenBarHCollection` properties:

</tbody>
</table>

these can either be a single argument, i.e.:

```
facecolors = 'black'
```

or a sequence of arguments for the various bars, i.e.:
facecolors = ('black', 'red', 'green')

Example:

```
0 25 50 75 100 125 150 175 200
seconds since start
Bill
Jim
```

Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All positional and all keyword arguments.

**matplotlib.pyplot.cla()**

Clear the current axes.

**matplotlib.pyplot.clabel(CS, *args, **kwargs)**

Label a contour plot.

Call signature:

```
clabel(cs, **kwargs)
```

Adds labels to line contours in cs, where cs is a ContourSet object returned by contour.

```
clabel(cs, v, **kwargs)
```

only labels contours listed in v.
Optional keyword arguments:

* **fontsize:** size in points or relative size e.g., ‘smaller’, ‘x-large’

* **colors:**
  - if *None*, the color of each label matches the color of the corresponding contour
  - if one string color, e.g., `colors = ‘r’` or `colors = ‘red’`, all labels will be plotted in this color
  - if a tuple of matplotlib color args (string, float, rgb, etc), different labels will be plotted in different colors in the order specified

* **inline:** controls whether the underlying contour is removed or not. Default is *True*.

* **inline_spacing:** space in pixels to leave on each side of label when placing inline. Defaults to 5. This spacing will be exact for labels at locations where the contour is straight, less so for labels on curved contours.

* **fmt:** a format string for the label. Default is ‘%1.3f’ Alternatively, this can be a dictionary matching contour levels with arbitrary strings to use for each contour level (i.e., `fmt[level]=string`), or it can be any callable, such as a *Formatter* instance, that returns a string when called with a numeric contour level.

* **manual:** if *True*, contour labels will be placed manually using mouse clicks. Click the first button near a contour to add a label, click the second button (or potentially both mouse buttons at once) to finish adding labels. The third button can be used to remove the last label added, but only if labels are not inline. Alternatively, the keyboard can be used to select label locations (enter to end label placement, delete or backspace act like the third mouse button, and any other key will select a label location).

  *manual* can be an iterable object of x,y tuples. Contour labels will be created as if mouse is clicked at each x,y positions.

* **rightside_up:** if *True* (default), label rotations will always be plus or minus 90 degrees from level.

* **use_clabeltext:** if *True* (default is False), ClabelText class (instead of matplotlib.Text) is used to create labels. ClabelText recalculates rotation angles of texts during the drawing time, therefore this can be used if aspect of the axes changes.
Simplest default with labels
Single color - negative contours dashed
Single color - negative contours solid
matplotlib.pyplot.clf()

Clear the current figure.

matplotlib.pyplot.clim(vmin=None, vmax=None)

Set the color limits of the current image.

To apply clim to all axes images do:

```python
clim(0, 0.5)
```

If either vmin or vmax is None, the image min/max respectively will be used for color scaling.

If you want to set the clim of multiple images, use, for example:

```python
for im in gca().get_images():
    im.set_clim(0, 0.05)
```

matplotlib.pyplot.close(*args)

Close a figure window.

close() by itself closes the current figure

close(h) where h is a Figure instance, closes that figure

close(num) closes figure number num

close(name) where name is a string, closes figure with that label
close('all') closes all the figure windows

```
matplotlib.pyplot.cohere(x, y, NFFT=256, Fs=2, Fc=0, detrend=<function detrend_none>,
window=<function window_hanning>, noverlap=0, pad_to=None,
sides='default', scale_by_freq=None, hold=None, data=None,
**kwargs)
```

Plot the coherence between $x$ and $y$.

Plot the coherence between $x$ and $y$. Coherence is the normalized cross spectral density:

$$C_{xy} = \frac{|P_{xy}|^2}{P_{xx}P_{yy}}$$  \hspace{1cm} (44.1)

**Parameters**

- **Fs**: scalar
  The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, `freqs`, in cycles per time unit. The default value is 2.

- **window**: callable or ndarray
  A function or a vector of length `NFFT`. To create window vectors see `window_hanning()`, `window_none()`, `numpy.blackman()`, `numpy.hamming()`, `numpy.bartlett()`, `scipy.signal()`, `scipy.signal.get_window()`, etc. The default is `window_hanning()`. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.

- **sides**: [‘default’ | ‘onesided’ | ‘twosided’]
  Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.

- **pad_to**: integer
  The number of points to which the data segment is padded when performing the FFT. This can be different from `NFFT`, which specifies the number of data points used. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the `n` parameter in the call to `fft()`. The default is None, which sets `pad_to` equal to `NFFT`

- **NFFT**: integer
  The number of data points used in each block for the FFT. A power 2 is most efficient. The default value is 256. This should NOT be used to get zero padding, or the scaling of the result will be incorrect. Use `pad_to` for this instead.

- **detrend**: {‘default’, ‘constant’, ‘mean’, ‘linear’, ‘none’} or callable
  The function applied to each segment before `fft-ing`, designed to remove the mean or linear trend. Unlike in MATLAB, where the `detrend` parameter is a vector, in matplotlib it is a function. The `pylab` module defines
detrend_none(), detrend_mean(), and detrend_linear(), but you can use a custom function as well. You can also use a string to choose one of the functions. ‘default’, ‘constant’, and ‘mean’ call detrend_mean(). ‘linear’ calls detrend_linear(). ‘none’ calls detrend_none().

scale_by_freq : boolean, optional

Specifies whether the resulting density values should be scaled by the scaling frequency, which gives density in units of Hz^-1. This allows for integration over the returned frequency values. The default is True for MATLAB compatibility.

noverlap : integer

The number of points of overlap between blocks. The default value is 0 (no overlap).

Fc : integer

The center frequency of x (defaults to 0), which offsets the x extents of the plot to reflect the frequency range used when a signal is acquired and then filtered and downsamped to baseband.

**kwargs :

Keyword arguments control the Line2D properties of the coherence plot:

**Returns** The return value is a tuple \((C_{xy}, f)\), where \(f\) are the frequencies of the coherence vector.
kwargvs are applied to the lines.

**References**

Examples

![Example plot](image)

**Note:** In addition to the above described arguments, this function can take a *data* keyword argument. If such a *data* argument is given, the following arguments are replaced by *data*[<arg>]:

- All arguments with the following names: ‘x’, ‘y’.

```python
matplotlib.pyplot.colorbar(mappable=None, cax=None, ax=None, **kwargs)
```

Add a colorbar to a plot.

Function signatures for the *pyplot* interface; all but the first are also method signatures for the `colorbar()` method:

- `colorbar(**kwargs)`
- `colorbar(mappable, **kwargs)`
- `colorbar(mappable, cax=cax, **kwargs)`
- `colorbar(mappable, ax=ax, **kwargs)`

Arguments:

- `mappable` the Image, ContourSet, etc. to which the colorbar applies; this argument is mandatory for the `colorbar()` method but optional for the `colorbar()` function, which sets the default to the current image.
keyword arguments:

**cax** None | axes object into which the colorbar will be drawn

**ax** None | parent axes object(s) from which space for a new colorbar axes will be stolen. If a list of axes is given they will all be resized to make room for the colorbar axes.

**use_gridspec** False | If cax is None, a new cax is created as an instance of Axes. If ax is an instance of Subplot and use_gridspec is True, cax is created as an instance of Subplot using the grid_spec module.

Additional keyword arguments are of two kinds:

**axes properties:**

<table>

</tr>
</tbody>
</table>

The following will probably be useful only in the context of indexed colors (that is, when the mappable has norm=NoNorm()), or other unusual circumstances.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>boundaries</td>
<td>None or a sequence</td>
</tr>
<tr>
<td>values</td>
<td>None or a sequence which must be of length 1 less than the sequence of boundaries. For each region delimited by adjacent entries in boundaries, the color mapped to the corresponding value in values will be used.</td>
</tr>
</tbody>
</table>

If mappable is a ContourSet, its extend kwarg is included automatically.

Note that the shrink kwarg provides a simple way to keep a vertical colorbar, for example, from being taller than the axes of the mappable to which the colorbar is attached; but it is a manual method requiring some trial and error. If the colorbar is too tall (or a horizontal colorbar is too wide) use a smaller value of shrink.

For more precise control, you can manually specify the positions of the axes objects in which the
mappable and the colorbar are drawn. In this case, do not use any of the axes properties kwargs.

It is known that some vector graphics viewer (svg and pdf) renders white gaps between segments of the colorbar. This is due to bugs in the viewers not matplotlib. As a workaround the colorbar can be rendered with overlapping segments:

```python
cbar = colorbar()
cbar.solids.set_edgecolor("face")
draw()
```

However this has negative consequences in other circumstances. Particularly with semi transparent images (alpha < 1) and colorbar extensions and is not enabled by default see (issue #1188).

**returns:** Colorbar instance; see also its base class, ColorbarBase. Call the set_label() method to label the colorbar.

```
matplotlib.pyplot.colors()
```

This is a do-nothing function to provide you with help on how matplotlib handles colors.

Commands which take color arguments can use several formats to specify the colors. For the basic built-in colors, you can use a single letter

```
<table>
<thead>
<tr>
<th>Alias</th>
<th>Color</th>
</tr>
</thead>
<tbody>
<tr>
<td>'b'</td>
<td>blue</td>
</tr>
<tr>
<td>'g'</td>
<td>green</td>
</tr>
<tr>
<td>'r'</td>
<td>red</td>
</tr>
<tr>
<td>'c'</td>
<td>cyan</td>
</tr>
<tr>
<td>'m'</td>
<td>magenta</td>
</tr>
<tr>
<td>'y'</td>
<td>yellow</td>
</tr>
<tr>
<td>'k'</td>
<td>black</td>
</tr>
<tr>
<td>'w'</td>
<td>white</td>
</tr>
</tbody>
</table>
```

For a greater range of colors, you have two options. You can specify the color using an html hex string, as in:

```python
color = '#eefeff'
```

or you can pass an R,G,B tuple, where each of R,G,B are in the range [0,1].

You can also use any legal html name for a color, for example:

```python
color = 'red'
color = 'burlywood'
color = 'chartreuse'
```

The example below creates a subplot with a dark slate gray background:

```python
subplot(111, facecolor=(0.1843, 0.3098, 0.3098))
```

Here is an example that creates a pale turquoise title:

```python
title('Is this the best color?', color='#afeeee')
```
```python
def func(event):
    def on_press(event):
        print('you pressed', event.button, event.xdata, event.ydata)
    cid = canvas.mpl_connect('button_press_event', on_press)
```

```python
matplotlib.pyplot.contour(*args, **kwargs)
```

Plot contours.

*contour()* and *contourf()* draw contour lines and filled contours, respectively. Except as noted, function signatures and return values are the same for both versions.

*contourf()* differs from the MATLAB version in that it does not draw the polygon edges. To draw edges, add line contours with calls to *contour()*.

Call signatures:
contour(Z)

make a contour plot of an array Z. The level values are chosen automatically.

contour(X,Y,Z)

X, Y specify the (x, y) coordinates of the surface

contour(Z,N)
contour(X,Y,Z,N)

countour up to N automatically-chosen levels.

contour(Z,V)
contour(X,Y,Z,V)

draw contour lines at the values specified in sequence V, which must be in increasing order.

contourf(..., V)

fill the len(V) - 1 regions between the values in V, which must be in increasing order.

contour(Z, **kwargs)

Use keyword args to control colors, linewidth, origin, cmap ... see below for more details.

X and Y must both be 2-D with the same shape as Z, or they must both be 1-D such that len(X) is the number of columns in Z and len(Y) is the number of rows in Z.

C = contour(...) returns a QuadContourSet object.

Optional keyword arguments:

corner_mask: [ True | False | ‘legacy’ ] Enable/disable corner masking, which only has an effect if Z is a masked array. If False, any quad touching a masked point is masked out. If True, only the triangular corners of quads nearest those points are always masked out, other triangular corners comprising three unmasked points are contoured as usual. If ‘legacy’, the old contouring algorithm is used, which is equivalent to False and is deprecated, only remaining whilst the new algorithm is tested fully.

If not specified, the default is taken from rcParams[‘contour.corner_mask’], which is True unless it has been modified.

colors: [ None | string | (mpl_colors) ] If None, the colormap specified by cmap will be used.

If a string, like ‘r’ or ‘red’, all levels will be plotted in this color.

If a tuple of matplotlib color args (string, float, rgb, etc), different levels will be plotted in different colors in the order specified.

alpha: float The alpha blending value
**Matplotlib, Release 2.0.0**

**cmap:** [None | Colormap] A `cm` `Colormap` instance or None. If `cmap` is None and `colors` is None, a default Colormap is used.

**norm:** [None | Normalize] A `matplotlib.colors.Normalize` instance for scaling data values to colors. If `norm` is None and `colors` is None, the default linear scaling is used.

**vmin, vmax:** [None | scalar] If not None, either or both of these values will be supplied to the `matplotlib.colors.Normalize` instance, overriding the default color scaling based on `levels`.

**levels:** [level0, level1, ..., leveln] A list of floating point numbers indicating the level curves to draw, in increasing order; e.g., to draw just the zero contour pass `levels=[0]`

**origin:** [None | ‘upper’ | ‘lower’ | ‘image’] If None, the first value of Z will correspond to the lower left corner, location (0,0). If ‘image’, the rc value for `image.origin` will be used.

This keyword is not active if X and Y are specified in the call to contour.

**extent:** [None | (x0, x1, y0, y1)]

If `origin` is not None, then `extent` is interpreted as in `matplotlib.pyplot.imshow()`: it gives the outer pixel boundaries. In this case, the position of Z[0,0] is the center of the pixel, not a corner. If `origin` is None, then (x0, y0) is the position of Z[0,0], and (x1, y1) is the position of Z[-1,-1].

This keyword is not active if X and Y are specified in the call to contour.

**locator:** [None | `ticker.Locator` subclass] If `locator` is None, the default `MaxNLocator` is used. The locator is used to determine the contour levels if they are not given explicitly via the V argument.

**extend:** ['neither' | ‘both’ | ‘min’ | ‘max’] Unless this is ‘neither’, contour levels are automatically added to one or both ends of the range so that all data are included. These added ranges are then mapped to the special colormap values which default to the ends of the colormap range, but can be set via `matplotlib.colors.Colormap.set_under()` and `matplotlib.colors.Colormap.set_over()` methods.

**xunits, yunits:** [None | registered units] Override axis units by specifying an instance of `matplotlib.units.ConversionInterface`.

**antialiased:** [True | False] enable antialiasing, overriding the defaults. For filled contours, the default is True. For line contours, it is taken from rc-Params['lines.antialiased'].

**nchunk:** [0 | integer] If 0, no subdivision of the domain. Specify a positive integer to divide the domain into subdomains of nchunk by nchunk quads. Chunking reduces the maximum length of polygons generated by the contouring algorithm which reduces the rendering workload passed on to the backend and also requires slightly less RAM. It can however introduce rendering artifacts at chunk boundaries depending on the backend, the antialiased flag and value of alpha.
contour-only keyword arguments:

**linewidths**: [ *None* | *number* | *tuple of numbers* ] If *linewidths* is *None*, the default width in *lines.linewidth* in *matplotlibrc* is used.

If a number, all levels will be plotted with this linewidth.

If a tuple, different levels will be plotted with different linewidths in the order specified.

**linestyles**: [ *None* | *‘solid’* | *‘dashed’* | *‘dashdot’* | *‘dotted’* ] If *linestyles* is *None*, the default is ‘solid’ unless the lines are monochrome. In that case, negative contours will take their linestyle from the *matplotlibrc* *contour.negative_linestyle* setting.

*linestyles* can also be an iterable of the above strings specifying a set of linestyles to be used. If this iterable is shorter than the number of contour levels it will be repeated as necessary.

contourf-only keyword arguments:

**hatches**: A list of cross hatch patterns to use on the filled areas. If *None*, no hatching will be added to the contour. Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

Note: contourf fills intervals that are closed at the top; that is, for boundaries $z_1$ and $z_2$, the filled region is:

\[
z_1 < z \leq z_2
\]

There is one exception: if the lowest boundary coincides with the minimum value of the $z$ array, then that minimum value will be included in the lowest interval.

**Examples:**
Simplest default with labels
Single color - negative contours dashed
Single color - negative contours solid
Listed colors (3 masked regions)
matplotlib.pyplot.contourf(*args, **kwargs)

Plot contours.

contour() and contourf() draw contour lines and filled contours, respectively. Except as noted, function signatures and return values are the same for both versions.

contourf() differs from the MATLAB version in that it does not draw the polygon edges. To draw edges, add line contours with calls to contour().

Call signatures:

contour(Z)

make a contour plot of an array Z. The level values are chosen automatically.

contour(X,Y,Z)

X, Y specify the (x, y) coordinates of the surface

contour(Z,N)
contour(X,Y,Z,N)

contour up to N automatically-chosen levels.

contour(Z,V)
contour(X,Y,Z,V)
draw contour lines at the values specified in sequence V, which must be in increasing order.

```
contourf(..., V)
```

fill the \texttt{len(V)-1} regions between the values in V, which must be in increasing order.

```
contour(Z, **kwargs)
```

Use keyword args to control colors, linewidth, origin, cmap ... see below for more details.

\(X\) and \(Y\) must both be 2-D with the same shape as \(Z\), or they must both be 1-D such that \(\text{len}(X)\) is the number of columns in \(Z\) and \(\text{len}(Y)\) is the number of rows in \(Z\).

\(C = \text{contour}(\ldots)\) returns a \texttt{QuadContourSet} object.

Optional keyword arguments:

- \texttt{corner\_mask: [ True | False | ‘legacy’ ]}\: Enable/disable corner masking, which only has an effect if \(Z\) is a masked array. If \texttt{False}, any quad touching a masked point is masked out. If \texttt{True}, only the triangular corners of quads nearest those points are always masked out, other triangular corners comprising three unmasked points are contoured as usual. If ‘legacy’, the old contouring algorithm is used, which is equivalent to \texttt{False}\ and is deprecated, only remaining whilst the new algorithm is tested fully.

  If not specified, the default is taken from \texttt{rcParams[‘contour.corner\_mask’]}, which is \texttt{True} unless it has been modified.

- \texttt{colors: [ None | string | (mpl\_colors) ]}\: If \texttt{None}, the colormap specified by \texttt{cmap} will be used.

  If a string, like ‘r’ or ‘red’, all levels will be plotted in this color.

  If a tuple of matplotlib color args (string, float, rgb, etc), different levels will be plotted in different colors in the order specified.

- \texttt{alpha: float}\: The alpha blending value

- \texttt{cmap: [ None | Colormap ]}\: A \texttt{cm Colormap} instance or \texttt{None}. If \texttt{cmap} is \texttt{None} and \texttt{colors} is \texttt{None}, a default Colormap is used.

- \texttt{norm: [ None | Normalize ]}\: A \texttt{matplotlib.colors.Normalize} instance for scaling data values to colors. If \texttt{norm} is \texttt{None} and \texttt{colors} is \texttt{None}, the default linear scaling is used.

- \texttt{vmin, vmax: [ None | scalar ]}\: If not \texttt{None}, either or both of these values will be supplied to the \texttt{matplotlib.colors.Normalize} instance, overriding the default color scaling based on \texttt{levels}.

- \texttt{levels: [level0, level1, ..., leveln]}\: A list of floating point numbers indicating the level curves to draw, in increasing order; e.g., to draw just the zero contour pass \texttt{levels=[0]}

- \texttt{origin: [ None | ‘upper’ | ‘lower’ | ‘image’ ]}\: If \texttt{None}, the first value of \(Z\) will correspond to the lower left corner, location \((0,0)\). If ‘image’, the \texttt{rc} value for \texttt{image.origin} will be used.
This keyword is not active if $X$ and $Y$ are specified in the call to contour.

**extent:** [None | (x0,x1,y0,y1)]

If `origin` is not `None`, then `extent` is interpreted as in `matplotlib.pyplot.imshow()`: it gives the outer pixel boundaries. In this case, the position of $Z[0,0]$ is the center of the pixel, not a corner. If `origin` is `None`, then $(x0, y0)$ is the position of $Z[0,0]$, and $(x1, y1)$ is the position of $Z[-1,-1]$.

This keyword is not active if $X$ and $Y$ are specified in the call to contour.

**locator:** [None | `ticker.Locator subclass`]

If `locator` is `None`, the default `MaxNLocator` is used. The locator is used to determine the contour levels if they are not given explicitly via the `V` argument.

**extend:** ['neither' | 'both' | 'min' | 'max']

Unless this is ‘neither’, contour levels are automatically added to one or both ends of the range so that all data are included. These added ranges are then mapped to the special colormap values which default to the ends of the colormap range, but can be set via `matplotlib.colors.Colormap.set_under()` and `matplotlib.colors.Colormap.set_over()` methods.

**xunits, yunits:** [None | registered units]

Override axis units by specifying an instance of a `matplotlib.units.ConversionInterface`.

**antialiased:** [True | False]

Enable antialiasing, overriding the defaults. For filled contours, the default is `True`. For line contours, it is taken from `rcParams['lines.antialiased']`.

**nchunk:** [0 | integer]

If 0, no subdivision of the domain. Specify a positive integer to divide the domain into subdomains of `nchunk` by `nchunk` quads. Chunking reduces the maximum length of polygons generated by the contouring algorithm which reduces the rendering workload passed on to the backend and also requires slightly less RAM. It can however introduce rendering artifacts at chunk boundaries depending on the backend, the antialiased flag and value of `alpha`.

Contour-only keyword arguments:

**linewidths:** [None | number | tuple of numbers]

If `linewidths` is `None`, the default width in `lines.linewidth` in `matplotlibrc` is used.

If a number, all levels will be plotted with this linewidth.

If a tuple, different levels will be plotted with different linewidths in the order specified.

**linestyles:** [None | ‘solid’ | ‘dashed’ | ‘dashdot’ | ‘dotted’]

If `linestyles` is `None`, the default is ‘solid’ unless the lines are monochrome. In that case, negative contours will take their linestyle from the `matplotlibrc contour.negative_linestyle` setting.

`linestyles` can also be an iterable of the above strings specifying a set of linestyles to be used. If this iterable is shorter than the number of contour levels it will be repeated as necessary.
contourf-only keyword arguments:

**hatches**: A list of cross hatch patterns to use on the filled areas. If None, no hatching will be added to the contour. Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

Note: contourf fills intervals that are closed at the top; that is, for boundaries $z_1$ and $z_2$, the filled region is:

$$z_1 < z \leq z_2$$

There is one exception: if the lowest boundary coincides with the minimum value of the $z$ array, then that minimum value will be included in the lowest interval.

**Examples:**
labels at selected locations
Single color - negative contours dashed
Single color - negative contours solid
Lines with colorbar
Listed colors (3 masked regions)
matplotlib.pyplot.cool()

set the default colormap to cool and apply to current image if any. See help(colormaps) for more information.

matplotlib.pyplot.copper()

set the default colormap to copper and apply to current image if any. See help(colormaps) for more information.

matplotlib.pyplot.csd(x, y, NFFT=None, Fs=None, Fc=0, detrend=mlab.detrend_none, window=mlab.window_hanning, noverlap=0, pad_to=None, sides='default', scale_by_freq=None, return_line=None, hold=None, data=None, **kwargs)

Plot the cross-spectral density.

Call signature:

csd(x, y, NFFT=256, Fs=2, Fc=0, detrend=mlab.detrend_none, window=mlab.window_hanning, noverlap=0, pad_to=None, sides='default', scale_by_freq=None, return_line=None, **kwargs)

The cross spectral density $P_{xy}$ by Welch’s average periodogram method. The vectors $x$ and $y$ are divided into $NFFT$ length segments. Each segment is detrended by function detrend and windowed by function window. noverlap gives the length of the overlap between segments. The product of the direct FFTs of $x$ and $y$ are averaged over each segment to compute $P_{xy}$, with a scaling to correct for power loss due to windowing.

If len(x) < NFFT or len(y) < NFFT, they will be zero padded to NFFT.
Parameters $x, y$: 1-D arrays or sequences

Arrays or sequences containing the data

$Fs$: scalar

The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, freqs, in cycles per time unit. The default value is 2.

$window$: callable or ndarray

A function or a vector of length $NFFT$. To create window vectors see `window_hanning()`, `window_none()`, `numpy.blackman()`, `numpy.hamming()`, `numpy.bartlett()`, `scipy.signal()`, `scipy.signal.get_window()`, etc. The default is `window_hanning()`. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.

$sides$: [‘default’ | ‘onesided’ | ‘twosided’]

Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.

$pad_to$: integer

The number of points to which the data segment is padded when performing the FFT. This can be different from $NFFT$, which specifies the number of data points used. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the $n$ parameter in the call to $fft()$. The default is None, which sets $pad_to$ equal to $NFFT$.

$NFFT$: integer

The number of data points used in each block for the FFT. A power 2 is most efficient. The default value is 256. This should NOT be used to get zero padding, or the scaling of the result will be incorrect. Use $pad_to$ for this instead.

$detrend$: {‘default’, ‘constant’, ‘mean’, ‘linear’, ‘none’} or callable

The function applied to each segment before $fft$-ing, designed to remove the mean or linear trend. Unlike in MATLAB, where the $detrend$ parameter is a vector, in matplotlib is it a function. The $pylab$ module defines $detrend_none()$, $detrend_mean()$, and $detrend_linear()$, but you can use a custom function as well. You can also use a string to choose one of the functions. ‘default’, ‘constant’, and ‘mean’ call $detrend_mean()$. ‘linear’ calls $detrend_linear()$. ‘none’ calls $detrend_none()$.

$scale_by_freq$: boolean, optional

Specifies whether the resulting density values should be scaled by the scaling frequency, which gives density in units of Hz^-1. This allows for integra-
tion over the returned frequency values. The default is True for MATLAB compatibility.

**noverlap : integer**

The number of points of overlap between segments. The default value is 0 (no overlap).

**Fc : integer**

The center frequency of \( x \) (defaults to 0), which offsets the x extents of the plot to reflect the frequency range used when a signal is acquired and then filtered and downsampled to baseband.

**return_line : bool**

Whether to include the line object plotted in the returned values. Default is False.

**kwargs :**

Keyword arguments control the Line2D properties:

**Returns Pxy**: 1-D array

The values for the cross spectrum $P_{xy}$ before scaling (complex valued)

**freqs**: 1-D array

The frequencies corresponding to the elements in $P_{xy}$

**line**: a Line2D instance

The line created by this function. Only returned if return_line is True.

**See also:**

**psd()** *psd()* is the equivalent to setting $y=x$.

In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

* All arguments with the following names: ‘x’, ‘y’.

**Notes**

For plotting, the power is plotted as $10 \log_{10}(P_{xy})$ for decibels, though $P_{xy}$ itself is returned.

**References**

Examples

```python
matplotlib.pyplot.delaxes(*args)
Remove an axes from the current figure. If ax doesn’t exist, an error will be raised.

delaxes(): delete the current axes

matplotlib.pyplot.disconnect(cid)
Disconnect callback id cid

Example usage:

cid = canvas.mpl_connect('button_press_event', on_press)
#...later
canvas.mpl_disconnect(cid)

matplotlib.pyplot.draw()
Redraw the current figure.

This is used to update a figure that has been altered, but not automatically re-drawn. If interactive
mode is on (ion()), this should be only rarely needed, but there may be ways to modify the state of
a figure without marking it as stale. Please report these cases as bugs.

A more object-oriented alternative, given any Figure instance, fig, that was created using a pyplot
function, is:
```
Plot an errorbar graph.
Plot x versus y with error deltas in yerr and xerr. Vertical errorbars are plotted if yerr is not None. Horizontal errorbars are plotted if xerr is not None.

x, y, xerr, and yerr can all be scalars, which plots a single error bar at x, y.

**Parameters**

- **x**: scalar
- **y**: scalar
- **xerr/yerr**: scalar or array-like, shape(n,1) or shape(2,n), optional
  - If a scalar number, len(N) array-like object, or an Nx1 array-like object, errorbars are drawn at +/-value relative to the data. Default is None.
  - If a sequence of shape 2xN, errorbars are drawn at -row1 and +row2 relative to the data.
- **fmt**: plot format string, optional, default: None
  - The plot format symbol. If fmt is ‘none’ (case-insensitive), only the errorbars are plotted. This is used for adding errorbars to a bar plot, for example. Default is ‘’, an empty plot format string; properties are then identical to the defaults for *plot*().
- **ecolor**: mpl color, optional, default: None
  - A matplotlib color arg which gives the color the errorbar lines; if None, use the color of the line connecting the markers.
- **elinewidth**: scalar, optional, default: None
  - The linewidth of the errorbar lines. If None, use the linewidth.
- **capsize**: scalar, optional, default: None
  - The length of the error bar caps in points; if None, it will take the value from *errorbar*.capsize *rcParam*.
- **capthick**: scalar, optional, default: None
  - An alias kwarg to markeredgewidth (a.k.a. - mew). This setting is a more sensible name for the property that controls the thickness of the error bar cap in points. For backwards compatibility, if mew or markeredgewidth are given, then they will over-ride capthick. This may change in future releases.
- **barsabove**: bool, optional, default: False
  - If True, will plot the errorbars above the plot symbols. Default is below.
lolims / uplims / xlolims / xuplims : bool, optional, default: None

These arguments can be used to indicate that a value gives only upper/lower
limits. In that case a caret symbol is used to indicate this. lims-arguments
may be of the same type as xerr and yerr. To use limits with inverted axes,
set_xlim() or set_ylim() must be called before errorbar().

errorevery : positive integer, optional, default: 1

subsamples the errorbars. e.g., if errorevery=5, errorbars for every 5-th data-
point will be plotted. The data plot itself still shows all data points.

Returns plotline : Line2D instance

x, y plot markers and/or line
caplines : list of Line2D instances
error bar cap
barlinecols : list of LineCollection
horizontal and vertical error ranges.

Other Parameters kwargs : All other keyword arguments are passed on to the plot
command for the markers. For example, this code makes big red squares
with thick green edges:

```python
x, y, yerr = rand(3, 10)
errorbar(x, y, yerr, marker='s', mfc='red', mec='green', ms=20, mew=4)
```

where mfc, mec, ms and mew are aliases for the longer property names,
markerfacecolor, markeredgecolor, markersize and markeredgewidth.

valid kwargs for the marker properties are

Examples

```
Note: In addition to the above described arguments, this function can take a data keyword argument.
If such a data argument is given, the following arguments are replaced by data[arg]:

• All arguments with the following names: ‘x’, ‘xerr’, ‘y’, ‘yerr’.

matplotlib.pyplot.eventplot(positions, orientation='horizontal', lineoffsets=1, line
lengths=1, linewidths=None, colors=None, linestyles='solid',
hold=None, data=None, **kwargs)
```

Plot identical parallel lines at specific positions.

Plot parallel lines at the given positions. positions should be a 1D or 2D array-like object, with each
row corresponding to a row or column of lines.

This type of plot is commonly used in neuroscience for representing neural events, where it is com-
monly called a spike raster, dot raster, or raster plot.

However, it is useful in any situation where you wish to show the timing or position of multiple sets
of discrete events, such as the arrival times of people to a business on each day of the month or the
date of hurricanes each year of the last century.

orientation[[ ‘horizontal’ | ‘vertical’ ] ‘horizontal’ : the lines will be vertical and arranged in rows
   ‘vertical’ : lines will be horizontal and arranged in columns}
`lineoffsets`: A float or array-like containing floats.

`linelengths`: A float or array-like containing floats.

`linewidths`: A float or array-like containing floats.

`colors` must be a sequence of RGBA tuples (e.g., arbitrary color strings, etc, not allowed) or a list of such sequences

`linestyles`: `[ 'solid' | 'dashed' | 'dashdot' | 'dotted' ]` or an array of these values

For linelengths, linewidths, colors, and linestyles, if only a single value is given, that value is applied to all lines. If an array-like is given, it must have the same length as positions, and each value will be applied to the corresponding row or column in positions.

Returns a list of `matplotlib.collections.EventCollection` objects that were added.

kwargs are `LineCollection` properties:

Example:

![Example Plot](image)

**Note:** In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

matplotlib.pyplot.figimage(*args, **kwargs)

Adds a non-resampled image to the figure.

call signatures:

```
figimage(X, **kwargs)
```

adds a non-resampled array X to the figure.

```
figimage(X, xo, yo)
```

with pixel offsets xo, yo,

X must be a float array:

- If X is MxN, assume luminance (grayscale)
- If X is MxNx3, assume RGB
- If X is MxNx4, assume RGBA

Optional keyword arguments:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>resize</td>
<td>a boolean, True or False. If “True”, then re-size the Figure to match the given image size.</td>
</tr>
<tr>
<td>xo or yo</td>
<td>An integer, the x and y image offset in pixels</td>
</tr>
<tr>
<td>cmap</td>
<td>a matplotlib.colors.Colormap instance, e.g., cm.jet. If None, default to the rc image.cmap value</td>
</tr>
<tr>
<td>norm</td>
<td>a matplotlib.colors.Normalize instance. The default is normalization(). This scales luminance -&gt; 0-1</td>
</tr>
<tr>
<td>vmin</td>
<td>unused to scale a luminance image to 0-1. If either is None, the min and max of the luminance values will be used. Note if you pass a norm instance, the settings for vmin and vmax will be ignored.</td>
</tr>
<tr>
<td>alpha</td>
<td>the alpha blending value, default is None</td>
</tr>
<tr>
<td>origin</td>
<td>[ ‘upper’</td>
</tr>
</tbody>
</table>

figimage complements the axes image (imshow()) which will be resampled to fit the current axes. If you want a resampled image to fill the entire figure, you can define an Axes with extent [0,0,1,1].

An matplotlib.image.FigureImage instance is returned.
Additional kwargs are Artist kwargs passed on to `FigureImage`.

`matplotlib.pyplot.figlegend(handles, labels, loc, **kwargs)`

Place a legend in the figure.

- **labels** a sequence of strings
- **handles** a sequence of `Line2D` or `Patch` instances
- **loc** can be a string or an integer specifying the legend location

A `matplotlib.legend.Legend` instance is returned.

Example:

```python
figlegend( (line1, line2, line3),
          ('label1', 'label2', 'label3'),
          'upper right' )
```

See also:

- `legend()`
- `matplotlib.pyplot.fignum_exists(num)`
- `matplotlib.pyplot.figtext(*args, **kwargs)`

Add text to figure.
Call signature:

```
    text(x, y, s, fontdict=None, **kwargs)
```

Add text to figure at location x, y (relative 0-1 coords). See `text()` for the meaning of the other arguments.

**kwargs control the `Text` properties:

</table>

**matplotlib.pyplot.figure**(num=None, figsize=None, dpi=None, facecolor=None, edgecolor=None, frameon=True, FigureClass=<class 'matplotlib.figure.Figure'>, **kwargs)

Creates a new figure.

**Parameters num** : integer or string, optional, default: none

If not provided, a new figure will be created, and the figure number will be incremented. The figure objects holds this number in a number attribute. If num is provided, and a figure with this id already exists, make it active, and returns a reference to it. If this figure does not exists, create it and returns it. If num is a string, the window title will be set to this figure’s num.

**figsize** : tuple of integers, optional, default: None

width, height in inches. If not provided, defaults to rc figure.figsize.

**dpi** : integer, optional, default: None

resolution of the figure. If not provided, defaults to rc figure.dpi.

**facecolor** :

the background color. If not provided, defaults to rc figure.facecolor

**edgecolor** :

the border color. If not provided, defaults to rc figure.edgecolor

**Returns figure** : Figure

The Figure instance returned will also be passed to new_figure_manager in the backends, which allows to hook custom Figure classes into the pylab interface. Additional kwargs will be passed to the figure init function.

**Notes**

If you are creating many figures, make sure you explicitly call “close” on the figures you are not using, because this will enable pylab to properly clean up the memory.

rcParams defines the default values, which can be modified in the matplotlib file
matplotlib.pyplot.fill(*args, **kwargs)

Plot filled polygons.

**Parameters**

*args: a variable length argument

It allowing for multiple x, y pairs with an optional color format string; see plot() for details on the argument parsing. For example, each of the following is legal:

```python
ax.fill(x, y)
ax.fill(x, y, "b")
ax.fill(x, y, "b", x, y, "r")
```

An arbitrary number of x, y, color groups can be specified: ax.fill(x1, y1, 'g', x2, y2, 'r')

**Returns** a list of Patch

**Other Parameters**

**kwargs**: Polygon properties

**Notes**

The same color strings that plot() supports are supported by the fill format string.

If you would like to fill below a curve, e.g., shade a region between 0 and y along x, use fill_between()
Examples

Note: In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]:`

- All arguments with the following names: ‘x’, ‘y’.

```
matplotlib.pyplot.fill_between(x, y1, y2=0, where=None, interpolate=False, step=None, hold=None, data=None, **kwargs)
```

Make filled polygons between two curves.

Create a `PolyCollection` filling the regions between $y_1$ and $y_2$ where $\text{where}==\text{True}$

**Parameters**

- **x**: array
  
  An N-length array of the x data

- **y1**: array
  
  An N-length array (or scalar) of the y data

- **y2**: array
  
  An N-length array (or scalar) of the y data

- **where**: array, optional
If `None`, default to fill between everywhere. If not `None`, it is an N-length numpy boolean array and the fill will only happen over the regions where `where==True`.

**interpolate**: bool, optional

If `True`, interpolate between the two lines to find the precise point of intersection. Otherwise, the start and end points of the filled region will only occur on explicit values in the `x` array.

**step**: {'pre', 'post', 'mid'}, optional

If not `None`, fill with step logic.

**See also:**

In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]: * All arguments with the following names: ‘where’, ‘x’, ‘y1’, ‘y2’.

**Notes**

Additional Keyword args passed on to the *PolyCollection*.

`**kwargs` control the *Polygon* properties:

**Examples**

![Graphs showing examples of different plots]

44.1. matplotlib.pyplot
Now regions with $y_2 > 1$ are masked.
matplotlib.pyplot.fill_betweenx(y, x1, x2=0, where=None, step=None, hold=None, data=None, **kwargs)

Make filled polygons between two horizontal curves.

Create a PolyCollection filling the regions between x1 and x2 where where==True

**Parameters**

`y` : array
  An N-length array of the y data

`x1` : array
  An N-length array (or scalar) of the x data

`x2` : array, optional
  An N-length array (or scalar) of the x data

`where` : array, optional
  If None, default to fill between everywhere. If not None, it is a N length numpy boolean array and the fill will only happen over the regions where where==True

`step` : {'pre', 'post', 'mid'}, optional
  If not None, fill with step logic.

**Examples**

![Diagram](image)
fill between where $\frac{y_2}{y_1} > 1$ are masked

```python
matplotlib.pyplot.findobj(o=None, match=None, include_self=True)
```

Find artist objects.

Recursively find all `Artist` instances contained in self.

`match` can be

- None: return all objects contained in artist.
- function with signature `boolean = match(artist)` used to filter matches
- class instance: e.g., `Line2D`. Only return artists of class type.

If `include_self` is True (default), include self in the list to be checked for a match.

```python
matplotlib.pyplot.flag()
```

set the default colormap to `flag` and apply to current image if any. See help(colormaps) for more information

```python
matplotlib.pyplot.gca(**kwargs)
```

Get the current `Axes` instance on the current figure matching the given keyword args, or create one.

See also:

```python
matplotlib.figure.Figure.gca
```
The figure’s `gca` method.
Examples

To get the current polar axes on the current figure:

```python
plt.gca(projection='polar')
```

If the current axes doesn’t exist, or isn’t a polar one, the appropriate axes will be created and then returned.

```python
matplotlib.pyplot.gcf()
```
Get a reference to the current figure.

```python
matplotlib.pyplot.gca()
```
Get the current colorable artist. Specifically, returns the current `ScalarMappable` instance (image or patch collection), or `None` if no images or patch collections have been defined. The commands `imshow()` and `figimage()` create `Image` instances, and the commands `pcolor()` and `scatter()` create `Collection` instances. The current image is an attribute of the current axes, or the nearest earlier axes in the current figure that contains an image.

```python
matplotlib.pyplot.get_current_fig_manager()
```

```python
matplotlib.pyplot.get_fignums()
```
Return a list of existing figure numbers.

```python
matplotlib.pyplot.get_figlabels()
```
Return a list of existing figure labels.

```python
matplotlib.pyplot.get_plot_commands()
```
Get a sorted list of all of the plotting commands.

```python
matplotlib.pyplot.ginput(*args, **kwargs)
```
Blocking call to interact with the figure. This will wait for $n$ clicks from the user and return a list of the coordinates of each click.

If `timeout` is zero or negative, does not timeout.

If $n$ is zero or negative, accumulate clicks until a middle click (or potentially both mouse buttons at once) terminates the input.

Right clicking cancels last input.

The buttons used for the various actions (adding points, removing points, terminating the inputs) can be overridden via the arguments `mouse_add`, `mouse_pop` and `mouse_stop`, that give the associated mouse button: 1 for left, 2 for middle, 3 for right.

The keyboard can also be used to select points in case your mouse does not have one or more of the buttons. The delete and backspace keys act like right clicking (i.e., remove last point), the enter key terminates input and any other key (not already used by the window manager) selects a point.

```python
matplotlib.pyplot.gray()
```
set the default colormap to gray and apply to current image if any. See `help(colormaps)` for more information.
matplotlib.pyplot.grid(b=None, which='major', axis='both', **kwargs)

Turn the axes grids on or off.

Set the axes grids on or off; b is a boolean. (For MATLAB compatibility, b may also be a string, ‘on’ or ‘off’.)

If b is None and len(kwargs)==0, toggle the grid state. If kwargs are supplied, it is assumed that you want a grid and b is thus set to True.

which can be ‘major’ (default), ‘minor’, or ‘both’ to control whether major tick grids, minor tick grids, or both are affected.

axis can be ‘both’ (default), ‘x’, or ‘y’ to control which set of gridlines are drawn.

kwargs are used to set the grid line properties, e.g.:

```
ax.grid(color='r', linestyle='--', linewidth=2)
```

Valid Line2D kwargs are

matplotlib.pyplot.hexbin(x, y, C=None, gridsize=100, bins=None, xscale='linear', yscale='linear', extent=None, cmap=None, norm=None, vmin=None, vmax=None, alpha=None, linewidths=None, edgecolors='none', reduce_C_function=<function mean>, mincnt=None, marginals=False, hold=None, data=None, **kwargs)

Make a hexagonal binning plot.

Make a hexagonal binning plot of x versus y, where x, y are 1-D sequences of the same length, N. If C is None (the default), this is a histogram of the number of occurrences of the observations at (x[i],y[i]).

If C is specified, it specifies values at the coordinate (x[i],y[i]). These values are accumulated for each hexagonal bin and then reduced according to reduce_C_function, which defaults to numpy’s mean function (np.mean). (If C is specified, it must also be a 1-D sequence of the same length as x and y.)

**Parameters**

- x, y : array or masked array
  - C : array or masked array, optional, default is None
  - gridsize : int or (int, int), optional, default is 100
    - The number of hexagons in the x-direction, default is 100. The corresponding number of hexagons in the y-direction is chosen such that the hexagons are approximately regular. Alternatively, gridsize can be a tuple with two elements specifying the number of hexagons in the x-direction and the y-direction.
  - bins : {'log'} or int or sequence, optional, default is None
    - If None, no binning is applied; the color of each hexagon directly corresponds to its count value.
    - If 'log', use a logarithmic scale for the color map. Internally, \(\log_{10}(i + 1)\) is used to determine the hexagon color.
    - If an integer, divide the counts in the specified number of bins, and color the hexagons accordingly.
If a sequence of values, the values of the lower bound of the bins to be used.

**xscale**: {'linear', 'log'}, optional, default is ‘linear’

Use a linear or log10 scale on the horizontal axis.

**yscale**: {'linear', 'log'}, optional, default is ‘linear’

Use a linear or log10 scale on the vertical axis.

**mincnt**: int > 0, optional, default is None

If not None, only display cells with more than mincnt number of points in the cell

**marginals**: bool, optional, default is False

if marginals is True, plot the marginal density as colormapped rectagles along the bottom of the x-axis and left of the y-axis

**extent**: scalar, optional, default is None

The limits of the bins. The default assigns the limits based on gridsize, x, y, xscale and yscale.

If xscale or yscale is set to ‘log’, the limits are expected to be the exponent for a power of 10. E.g. for x-limits of 1 and 50 in ‘linear’ scale and y-limits of 10 and 1000 in ‘log’ scale, enter (1, 50, 1, 3).

Order of scalars is (left, right, bottom, top).

**Returns** object

a PolyCollection instance; use get_array() on this PolyCollection to get the counts in each hexagon.

If marginals is True, horizontal bar and vertical bar (both PolyCollections) will be attached to the return collection as attributes hbar and vbar.

**Other Parameters**

**cmap**: object, optional, default is None

a matplotlib.colors.Colormap instance. If None, defaults to rc image.cmap.

**norm**: object, optional, default is None

matplotlib.colors.Normalize instance is used to scale luminance data to 0,1.

**vmin, vmax**: scalar, optional, default is None

vmin and vmax are used in conjunction with norm to normalize luminance data. If None, the min and max of the color array C are used. Note if you pass a norm instance your settings for vmin and vmax will be ignored.

**alpha**: scalar between 0 and 1, optional, default is None

the alpha value for the patches

**linewidths**: scalar, optional, default is None
If *None*, defaults to 1.0.

**edgecolors**: {'none'} or mpl color, optional, default is ‘none’

If ‘none’, draws the edges in the same color as the fill color. This is the default, as it avoids unsightly unpainted pixels between the hexagons.

If *None*, draws outlines in the default color.

If a matplotlib color arg, draws outlines in the specified color.

**Notes**

The standard descriptions of all the *Collection* parameters:

**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

- All arguments with the following names: ‘x’, ‘y’.

**Examples**

```python
import matplotlib.pyplot as plt

# Plot a histogram.

plt.hist(x, bins=None, range=None, normed=False, weights=None, cumulative=False, bottom=None, histtype='bar', align='mid', orientation='vertical', rwidth=None, log=False, color=None, label=None, stacked=False, hold=None, data=None, **kwargs)
```

Compute and draw the histogram of `x`. The return value is a tuple `(n, bins, patches)` or `[n0, n1, ...], bins, [patches0, patches1, ...]) if the input contains multiple data.

Multiple data can be provided via `x` as a list of datasets of potentially different length `(x0, x1, ...)`, or as a 2-D ndarray in which each column is a dataset. Note that the ndarray form is transposed relative
to the list form.

Masked arrays are not supported at present.

**Parameters**

- **x**: (n,) array or sequence of (n,) arrays
  
  Input values, this takes either a single array or a sequence of arrays which are not required to be of the same length

- **bins**: integer or array_like or ‘auto’, optional
  
  If an integer is given, bins + 1 bin edges are returned, consistently with `numpy.histogram()` for numpy version >= 1.3.

  Unequally spaced bins are supported if bins is a sequence.

  If Numpy 1.11 is installed, may also be 'auto'.

  Default is taken from the rcParam `hist.bins`.

- **range**: tuple or None, optional
  
  The lower and upper range of the bins. Lower and upper outliers are ignored. If not provided, range is (x.min(), x.max()). Range has no effect if bins is a sequence.

  If bins is a sequence or range is specified, autoscaling is based on the specified bin range instead of the range of x.

  Default is None

- **normed**: boolean, optional
  
  If True, the first element of the return tuple will be the counts normalized to form a probability density, i.e., \( \frac{n}{\text{len}(x) \cdot \text{dbin}} \), i.e., the integral of the histogram will sum to 1. If stacked is also True, the sum of the histograms is normalized to 1.

  Default is False

- **weights**: (n,) array_like or None, optional
  
  An array of weights, of the same shape as x. Each value in x only contributes its associated weight towards the bin count (instead of 1). If normed is True, the weights are normalized, so that the integral of the density over the range remains 1.

  Default is None

- **cumulative**: boolean, optional
  
  If True, then a histogram is computed where each bin gives the counts in that bin plus all bins for smaller values. The last bin gives the total number of datapoints. If normed is also True then the histogram is normalized such that the last bin equals 1. If cumulative evaluates to less than 0 (e.g., -1), the direction of accumulation is reversed. In this case, if normed is also True, then the histogram is normalized such that the first bin equals 1.
Default is False

**bottom**: array_like, scalar, or None

Location of the bottom baseline of each bin. If a scalar, the base line for each bin is shifted by the same amount. If an array, each bin is shifted independently and the length of bottom must match the number of bins. If None, defaults to 0.

Default is None

**histtype**: \{‘bar’, ‘barstacked’, ‘step’, ‘stepfilled’\}, optional

The type of histogram to draw.

- ‘bar’ is a traditional bar-type histogram. If multiple data are given the bars are aranged side by side.
- ‘barstacked’ is a bar-type histogram where multiple data are stacked on top of each other.
- ‘step’ generates a lineplot that is by default unfilled.
- ‘stepfilled’ generates a lineplot that is by default filled.

Default is ‘bar’

**align**: \{‘left’, ‘mid’, ‘right’\}, optional

Controls how the histogram is plotted.

- ‘left’: bars are centered on the left bin edges.
- ‘mid’: bars are centered between the bin edges.
- ‘right’: bars are centered on the right bin edges.

Default is ‘mid’

**orientation**: \{‘horizontal’, ‘vertical’\}, optional

If ‘horizontal’, barh will be used for bar-type histograms and the bottom kwarg will be the left edges.

**rwidth**: scalar or None, optional

The relative width of the bars as a fraction of the bin width. If None, automatically compute the width.

Ignored if histtype is ‘step’ or ‘stepfilled’.

Default is None

**log**: boolean, optional

If True, the histogram axis will be set to a log scale. If log is True and x is a 1D array, empty bins will be filtered out and only the non-empty (n, bins, patches) will be returned.

Default is False
**color** : color or array_like of colors or None, optional

Color spec or sequence of color specs, one per dataset. Default (None) uses the standard line color sequence.

Default is None

**label** : string or None, optional

String, or sequence of strings to match multiple datasets. Bar charts yield multiple patches per dataset, but only the first gets the label, so that the legend command will work as expected.

default is None

**stacked** : boolean, optional

If True, multiple data are stacked on top of each other If False multiple data are arranged side by side if histtype is ‘bar’ or on top of each other if histtype is ‘step’

Default is False

**Returns n** : array or list of arrays

The values of the histogram bins. See normed and weights for a description of the possible semantics. If input x is an array, then this is an array of length nbins. If input is a sequence arrays [data1, data2,..], then this is a list of arrays with the values of the histograms for each of the arrays in the same order.

**bins** : array

The edges of the bins. Length nbins + 1 (nbins left edges and right edge of last bin). Always a single array even when multiple data sets are passed in.

**patches** : list or list of lists

Silent list of individual patches used to create the histogram or list of such list if multiple input datasets.

**Other Parameters kwargs** : Patch properties

See also:

hist2d 2D histograms

**Notes**

Until numpy release 1.5, the underlying numpy histogram function was incorrect with normed=`True` if bin sizes were unequal. MPL inherited that error. It is now corrected within MPL when using earlier numpy versions.
Examples

Histogram of IQ: $\mu = 100, \sigma = 15$

Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: ‘weights’, ‘x’.

```python
matplotlib.pyplot.hist2d(x, y, bins=10, range=None, normed=False, weights=None, cmin=None, cmax=None, hold=None, data=None, **kwargs)
```

Make a 2D histogram plot.

Parameters x, y: array_like, shape (n, )

Input values

bins: [None | int | [int, int] | array_like | [array, array]]

The bin specification:

- If int, the number of bins for the two dimensions (nx=ny=bins).
- If [int, int], the number of bins in each dimension (nx, ny = bins).
- If array_like, the bin edges for the two dimensions (x_edges=y_edges=bins).
If [array, array], the bin edges in each dimension (x_edges, y_edges = bins).

The default value is 10.

**range**: array_like shape(2, 2), optional, default: None

The leftmost and rightmost edges of the bins along each dimension (if not specified explicitly in the bins parameters): [[xmin, xmax], [ymin, ymax]]. All values outside of this range will be considered outliers and not tallied in the histogram.

**normed**: boolean, optional, default: False

Normalize histogram.

**weights**: array_like, shape (n,), optional, default: None

An array of values w_i weighing each sample (x_i, y_i).

**cmin**: scalar, optional, default: None

All bins that has count less than cmin will not be displayed and these count values in the return value count histogram will also be set to nan upon return

**cmax**: scalar, optional, default: None

All bins that has count more than cmax will not be displayed (set to none before passing to imshow) and these count values in the return value count histogram will also be set to nan upon return

**Returns**
The return value is (counts, xedges, yedges, Image).

**Other Parameters**
**kwargs**: pcolorfast() properties.

**See also:**

**hist**: 1D histogram

**Notes**

Rendering the histogram with a logarithmic color scale is accomplished by passing a colors.LogNorm instance to the norm keyword argument. Likewise, power-law normalization (similar in effect to gamma correction) can be accomplished with colors.PowerNorm.
Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: ‘weights’, ‘x’, ‘y’.

matplotlib.pyplot.hlines(y, xmin, xmax, colors='k', linestyles='solid', label='', hold=None, data=None, **kwargs)
Plot horizontal lines at each y from xmin to xmax.

Parameters

- y : scalar or sequence of scalar
  y-indexes where to plot the lines.
- xmin, xmax : scalar or 1D array_like
  Respective beginning and end of each line. If scalars are provided, all lines will have same length.
- colors : array_like of colors, optional, default: ‘k’
- linestyles : [‘solid’ | ‘dashed’ | ‘dashdot’ | ‘dotted’], optional
- label : string, optional, default: ‘’
Returns lines: \texttt{LineCollection}

Other Parameters \texttt{kwargs}: \texttt{LineCollection} properties.

See also:

\texttt{vlines} vertical lines

\textbf{Examples}

\begin{center}
\begin{tabular}{cc}
\textbf{Vertical lines demo} & \textbf{Horizontal lines demo} \\
\includegraphics[width=0.4\textwidth]{vertical_lines_demo.png} & \includegraphics[width=0.4\textwidth]{horizontal_lines_demo.png}
\end{tabular}
\end{center}

\textbf{Note:} In addition to the above described arguments, this function can take a \texttt{data} keyword argument. If such a \texttt{data} argument is given, the following arguments are replaced by \texttt{data[<arg>]}:

- All arguments with the following names: ‘xmax’, ‘xmin’, ‘y’.

\begin{verbatim}
matplotlib.pyplot.hold(b=None)
\end{verbatim}

Deprecated since version 2.0: pyplot.hold is deprecated. Future behavior will be consistent with the long-time default: plot commands add elements without first clearing the Axes and/or Figure.

Set the hold state. If \texttt{b} is None (default), toggle the hold state, else set the hold state to boolean value \texttt{b}:

\begin{verbatim}
hold()  # toggle hold
hold(True)  # hold is on
hold(False)  # hold is off
\end{verbatim}

When \texttt{hold} is \texttt{True}, subsequent plot commands will add elements to the current axes. When \texttt{hold} is \texttt{False}, the current axes and figure will be cleared on the next plot command.

\begin{verbatim}
matplotlib.pyplot.hot()
\end{verbatim}

set the default colormap to hot and apply to current image if any. See help(colormaps) for more
Matplotlib, Release 2.0.0

information

matplotlib.pyplot.hsv()
set the default colormap to hsv and apply to current image if any. See help(colormaps) for more information

matplotlib.pyplot.imread(*args, **kwargs)
Read an image from a file into an array.

 fname may be a string path, a valid URL, or a Python file-like object. If using a file object, it must be opened in binary mode.

If format is provided, will try to read file of that type, otherwise the format is deduced from the filename. If nothing can be deduced, PNG is tried.

Return value is a numpy.array. For grayscale images, the return array is MxN. For RGB images, the return value is MxNx3. For RGBA images the return value is MxNx4.

matplotlib can only read PNGs natively, but if PIL is installed, it will use it to load the image and return an array (if possible) which can be used with imshow(). Note, URL strings may not be compatible with PIL. Check the PIL documentation for more information.

matplotlib.pyplot.imsave(*args, **kwargs)
Save an array as in image file.

The output formats available depend on the backend being used.

Arguments:

 fname: A string containing a path to a filename, or a Python file-like object. If format is None and fname is a string, the output format is deduced from the extension of the filename.

 arr: An MxN (luminance), MxNx3 (RGB) or MxNx4 (RGBA) array.

Keyword arguments:

 vmin/vmax: [ None | scalar ] vmin and vmax set the color scaling for the image by fixing the values that map to the colormap color limits. If either vmin or vmax is None, that limit is determined from the arr min/max value.

cmap: cmap is a colors.Colormap instance, e.g., cm.jet. If None, default to the rc image.cmap value.

format: One of the file extensions supported by the active backend. Most backends support png, pdf, ps, eps and svg.

origin ['upper' | 'lower'] Indicates where the [0,0] index of the array is in the upper left or lower left corner of the axes. Defaults to the rc image.origin value.

dpi The DPI to store in the metadata of the file. This does not affect the resolution of the output image.

matplotlib.pyplot.imshow(X, cmap=None, norm=None, aspect=None, interpolation=None, alpha=None, vmin=None, vmax=None, origin=None, extent=None, shape=None, filternorm=1, filterrad=4.0, imlim=None, resample=None, url=None, hold=None, data=None, **kwargs)
Display an image on the axes.
Parameters X: array_like, shape (n, m) or (n, m, 3) or (n, m, 4)

Display the image in X to current axes. X may be an array or a PIL image. If X is an array, it can have the following shapes and types:

- MxN – values to be mapped (float or int)
- MxNx3 – RGB (float or uint8)
- MxNx4 – RGBA (float or uint8)

The value for each component of MxNx3 and MxNx4 float arrays should be in the range 0.0 to 1.0. MxN arrays are mapped to colors based on the norm (mapping scalar to scalar) and the cmap (mapping the normed scalar to a color).

cmap: Colormap, optional, default: None

If None, default to rc image.cmap value. cmap is ignored if X is 3-D, directly specifying RGB(A) values.

aspect: [’auto’ | ’equal’ | scalar], optional, default: None

If ‘auto’, changes the image aspect ratio to match that of the axes.

If ‘equal’, and extent is None, changes the axes aspect ratio to match that of the image. If extent is not None, the axes aspect ratio is changed to match that of the extent.

If None, default to rc image.aspect value.

interpolation: string, optional, default: None

If interpolation is None, default to rc image.interpolation. See also the filternorm and filterrad parameters. If interpolation is ‘none’, then no interpolation is performed on the Agg, ps and pdf backends. Other backends will fall back to ‘nearest’.

norm: Normalize, optional, default: None

A Normalize instance is used to scale a 2-D float X input to the (0, 1) range for input to the cmap. If norm is None, use the default func:normalize. If norm is an instance of NoNorm, X must be an array of integers that index directly into the lookup table of the cmap.

vmin, vmax: scalar, optional, default: None

vmin and vmax are used in conjunction with norm to normalize luminance data. Note if you pass a norm instance, your settings for vmin and vmax will be ignored.

alpha: scalar, optional, default: None

The alpha blending value, between 0 (transparent) and 1 (opaque)
origin : ['upper' | 'lower'], optional, default: None

Place the [0,0] index of the array in the upper left or lower left corner of the axes. If None, default to rc image.origin.

extent : scalars (left, right, bottom, top), optional, default: None

The location, in data-coordinates, of the lower-left and upper-right corners. If None, the image is positioned such that the pixel centers fall on zero-based (row, column) indices.

shape : scalars (columns, rows), optional, default: None

For raw buffer images

filternorm : scalar, optional, default: 1

A parameter for the antigrain image resize filter. From the antigrain documentation, if filternorm = 1, the filter normalizes integer values and corrects the rounding errors. It doesn’t do anything with the source floating point values, it corrects only integers according to the rule of 1.0 which means that any sum of pixel weights must be equal to 1.0. So, the filter function must produce a graph of the proper shape.

filterrad : scalar, optional, default: 4.0

The filter radius for filters that have a radius parameter, i.e. when interpolation is one of: ‘sinc’, ‘lanczos’ or ‘blackman’

Returns image : AxesImage

Other Parameters kwargs : Artist properties.

See also:

matshow Plot a matrix or an array as an image.

Notes

Unless extent is used, pixel centers will be located at integer coordinates. In other words: the origin will coincide with the center of pixel (0, 0).
Note: In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

- All positional and all keyword arguments.

```python
matplotlib.pyplot.inferno()
```
set the default colormap to inferno and apply to current image if any. See help(colormaps) for more information.

```python
matplotlib.pyplot.install_repl_displayhook()
```
Install a repl display hook so that any stale figure are automatically redrawn when control is returned to the repl.

This works with IPython terminals and kernels, as well as vanilla python shells.

```python
matplotlib.pyplot.ioff()
```
Turn interactive mode off.

```python
matplotlib.pyplot.ion()
```
Turn interactive mode on.

```python
matplotlib.pyplot.ishold()
```
Deprecation notice: pyplot.hold is deprecated. Future behavior will be consistent with the long-time default: plot commands add elements without first clearing the Axes and/or Figure.

Return the hold status of the current axes.

```python
matplotlib.pyplot.isinteractive()
```

Return status of interactive mode.

```python
matplotlib.pyplot.jet()
```

Set the default colormap to jet and apply to current image if any. See help(colormaps) for more information.

```python
matplotlib.pyplot.legend(*args, **kwargs)
```

Places a legend on the axes.

To make a legend for lines which already exist on the axes (via plot for instance), simply call this function with an iterable of strings, one for each legend item. For example:

```python
ax.plot([1, 2, 3])
ax.legend(['A simple line'])
```

However, in order to keep the “label” and the legend element instance together, it is preferable to specify the label either at artist creation, or by calling the `set_label()` method on the artist:

```python
line, = ax.plot([1, 2, 3], label='Inline label')
# Overwrite the label by calling the method.
line.set_label('Label via method')
ax.legend()
```

Specific lines can be excluded from the automatic legend element selection by defining a label starting with an underscore. This is default for all artists, so calling `legend()` without any arguments and without setting the labels manually will result in no legend being drawn.

For full control of which artists have a legend entry, it is possible to pass an iterable of legend artists followed by an iterable of legend labels respectively:

```python
legend((line1, line2, line3), ('label1', 'label2', 'label3'))
```

**Parameters**

`loc`: int or string or pair of floats, default: ‘upper right’

The location of the legend. Possible codes are:
<table>
<thead>
<tr>
<th>Location String</th>
<th>Location Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘best’</td>
<td>0</td>
</tr>
<tr>
<td>‘upper right’</td>
<td>1</td>
</tr>
<tr>
<td>‘upper left’</td>
<td>2</td>
</tr>
<tr>
<td>‘lower left’</td>
<td>3</td>
</tr>
<tr>
<td>‘lower right’</td>
<td>4</td>
</tr>
<tr>
<td>‘right’</td>
<td>5</td>
</tr>
<tr>
<td>‘center left’</td>
<td>6</td>
</tr>
<tr>
<td>‘center right’</td>
<td>7</td>
</tr>
<tr>
<td>‘lower center’</td>
<td>8</td>
</tr>
<tr>
<td>‘upper center’</td>
<td>9</td>
</tr>
<tr>
<td>‘center’</td>
<td>10</td>
</tr>
</tbody>
</table>

Alternatively can be a 2-tuple giving $x$, $y$ of the lower-left corner of the legend in axes coordinates (in which case `bbox_to_anchor` will be ignored).

**bbox_to_anchor**: `matplotlib.transforms.BboxBase` instance or tuple of floats

Specify any arbitrary location for the legend in `bbox_transform` coordinates (default Axes coordinates).

For example, to put the legend’s upper right hand corner in the center of the axes the following keywords can be used:

```python
loc='upper right', bbox_to_anchor=(0.5, 0.5)
```

**ncol**: integer

The number of columns that the legend has. Default is 1.

**prop**: None or `matplotlib.font_manager.FontProperties` or dict

The font properties of the legend. If None (default), the current `matplotlib.rcParams` will be used.

**fontsize**: int or float or {'xx-small', 'x-small', 'small', 'medium', 'large', 'x-large', 'xx-large'}

Controls the font size of the legend. If the value is numeric the size will be the absolute font size in points. String values are relative to the current default font size. This argument is only used if `prop` is not specified.

**numpoints**: None or int

The number of marker points in the legend when creating a legend entry for a `matplotlib.lines.Line2D`. Default is None which will take the value from the `legend.numpoints` rcParam.

**scatterpoints**: None or int

The number of marker points in the legend when creating a legend entry for a scatter plot/ `matplotlib.collections.PathCollection`. Default is None which will take the value from the `legend.scatterpoints` rcParam.

**scatteryoffsets**: iterable of floats
The vertical offset (relative to the font size) for the markers created for a scatter plot legend entry. 0.0 is at the base the legend text, and 1.0 is at the top. To draw all markers at the same height, set to [0.5]. Default [0.375, 0.5, 0.3125].

**markerscale**: None or int or float

The relative size of legend markers compared with the originally drawn ones. Default is `None` which will take the value from the `legend.markerscale rcParam`.

**markerfirst**: bool

If `True`, legend marker is placed to the left of the legend label if `False`, legend marker is placed to the right of the legend label

**frameon**: None or bool

Control whether the legend should be drawn on a patch (frame). Default is `None` which will take the value from the `legend.frameon rcParam`.

**fancybox**: None or bool

Control whether round edges should be enabled around the `FancyBboxPatch` which makes up the legend’s background. Default is `None` which will take the value from the `legend.fancybox rcParam`.

**shadow**: None or bool

Control whether to draw a shadow behind the legend. Default is `None` which will take the value from the `legend.shadow rcParam`.

**framealpha**: None or float

Control the alpha transparency of the legend’s background. Default is `None` which will take the value from the `legend.framealpha rcParam`.

**facecolor**: None or “inherit” or a color spec

Control the legend’s background color. Default is `None` which will take the value from the `legend.facecolor rcParam`. If "inherit", it will take the `axes.facecolor rcParam`.

**edgecolor**: None or “inherit” or a color spec

Control the legend’s background patch edge color. Default is `None` which will take the value from the `legend.edgecolor rcParam`. If "inherit", it will take the `axes.edgecolor rcParam`.

**mode**: {“expand”, `None`}

If `mode` is set to "expand" the legend will be horizontally expanded to fill the axes area (or `bbox_to_anchor` if defines the legend’s size).

**bbox_transform**: None or `matplotlib.transforms.Transform`

The transform for the bounding box (`bbox_to_anchor`). For a value of `None` (default) the Axes’ `transAxes` transform will be used.
**title**: str or None

The legend’s title. Default is no title (None).

**borderpad**: float or None

The fractional whitespace inside the legend border. Measured in font-size units. Default is None which will take the value from the `legend.borderpad` rcParam.

**labelspacing**: float or None

The vertical space between the legend entries. Measured in font-size units. Default is None which will take the value from the `legend.labelspacing` rcParam.

**handlelength**: float or None

The length of the legend handles. Measured in font-size units. Default is None which will take the value from the `legend.handlelength` rcParam.

**handletextpad**: float or None

The pad between the legend handle and text. Measured in font-size units. Default is None which will take the value from the `legend.handletextpad` rcParam.

**borderaxespad**: float or None

The pad between the axes and legend border. Measured in font-size units. Default is None which will take the value from the `legend.borderaxespad` rcParam.

**columnspacing**: float or None

The spacing between columns. Measured in font-size units. Default is None which will take the value from the `legend.columnspacing` rcParam.

**handler_map**: dict or None

The custom dictionary mapping instances or types to a legend handler. This `handler_map` updates the default handler map found at `matplotlib.legend.Legend.get_legend_handler_map()`.

**Notes**

Not all kinds of artist are supported by the legend command. See `Legend guide` for details.
Examples

```
import matplotlib.pyplot as plt

ax = plt.gca()  # Get current axes

# Example of using locator_params
ax.locator_params(tight=True, nbins=4)
```

```
plt.show()
```

**matplotlib.pyplot.locator_params** *(axis=’both’, tight=None, **kwargs)*

Control behavior of tick locators.

Keyword arguments:

- **axis** ['x' | 'y' | 'both'] Axis on which to operate; default is ‘both’.
- **tight** [True | False | None] Parameter passed to autoscale_view(). Default is None, for no change.

Remaining keyword arguments are passed to directly to the set_params() method.

Typically one might want to reduce the maximum number of ticks and use tight bounds when plotting small subplots, for example:

```
ax.locator_params(tight=True, nbins=4)
```

Because the locator is involved in autoscaling, autoscale_view() is called automatically after the parameters are changed.

This presently works only for the MaxNLocator used by default on linear axes, but it may be generalized.

```
import matplotlib.pyplot as plt

plt.loglog(*args, **kwargs)
```

Make a plot with log scaling on both the x and y axis.
loglog() supports all the keyword arguments of plot() and matplotlib.axes.Axes.set_xscale() / matplotlib.axes.Axes.set_yscale.

Notable keyword arguments:

* **basex/basey**: scalar > 1 Base of the x/y logarithm

* **subsx/subsy**: [None | sequence] The location of the minor x/y ticks; None defaults to autosubs, which depend on the number of decades in the plot; see matplotlib.axes.Axes.set_xscale() / matplotlib.axes.Axes.set_yscale() for details

* **nonposx/nonposy**: ['mask' | 'clip'] Non-positive values in x or y can be masked as invalid, or clipped to a very small positive number

The remaining valid kwargs are Line2D properties:

Example:

```python
import matplotlib.pyplot as plt
plt.magma()  # set the default colormap to magma and apply to current image if any. See help(colormaps) for more information
```

```python
plt.magnitude_spectrum(x, Fs=None, Fc=None, window=None, pad_to=None, sides=None, scale=None, hold=None, data=None, **kwargs)
```

Errorbars go negative
Plot the magnitude spectrum.

Call signature:

```python
magnitude_spectrum(x, Fs=2, Fc=0, window=mlab.window_hanning,
                   pad_to=None, sides='default', **kwargs)
```

Compute the magnitude spectrum of `x`. Data is padded to a length of `pad_to` and the windowing function `window` is applied to the signal.

**Parameters**

- **x**: 1-D array or sequence
  - Array or sequence containing the data

- **Fs** : scalar
  - The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, `freqs`, in cycles per time unit. The default value is 2.

- **window** : callable or ndarray
  - A function or a vector of length `NFFT`. To create window vectors see `window_hanning()`, `window_none()`, `numpy.blackman()`, `numpy.hamming()`, `numpy.bartlett()`, `scipy.signal()`, etc. The default is `window_hanning()`. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.

- **sides** : [‘default’ | ‘onesided’ | ‘twosided’]
  - Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.

- **pad_to** : integer
  - The number of points to which the data segment is padded when performing the FFT. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the `n` parameter in the call to `fft()`. The default is `None`, which sets `pad_to` equal to the length of the input signal (i.e. no padding).

- **scale** : [‘default’ | ‘linear’ | ‘dB’]
  - The scaling of the values in the `spec`. ‘linear’ is no scaling. ‘dB’ returns the values in dB scale. When `mode` is ‘density’, this is dB power (10 * log10). Otherwise this is dB amplitude (20 * log10). ‘default’ is ‘linear’.

- **Fc** : integer
  - The center frequency of `x` (defaults to 0), which offsets the x extents of the plot to reflect the frequency range used when a signal is acquired and then filtered and downsampled to baseband.
**kwargs:

Keyword arguments control the *Line2D* properties:

<table>

</tbody>
</table>
Returns spectrum : 1-D array

The values for the magnitude spectrum before scaling (real valued)

freqs : 1-D array

The frequencies corresponding to the elements in spectrum

line : a Line2D instance

The line created by this function

See also:

psd() psd() plots the power spectral density.

angle_spectrum() angle_spectrum() plots the angles of the corresponding frequencies.

phase_spectrum() phase_spectrum() plots the phase (unwrapped angle) of the corresponding frequencies.

specgram() specgram() can plot the magnitude spectrum of segments within the signal in a colormap.

In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]: * All arguments with the following names: ‘x’.
matplotlib.pyplot.margins(*args, **kw)

Set or retrieve autoscaling margins.

signatures:

margins()

returns xmargin, ymargin

margins(margin)
margins(xmargin, ymargin)
margins(x=xmargin, y=ymargin)
margins(..., tight=False)

All three forms above set the xmargin and ymargin parameters. All keyword parameters are optional. A single argument specifies both xmargin and ymargin. The tight parameter is passed to autoscale_view(), which is executed after a margin is changed; the default here is True, on the assumption that when margins are specified, no additional padding to match tick marks is usually desired. Setting tight to None will preserve the previous setting.
Specifying any margin changes only the autoscaling; for example, if `xmargin` is not `None`, then `xmargin` times the X data interval will be added to each end of that interval before it is used in autoscaling.

```python
matplotlib.pyplot.matshow(A, fignum=None, **kw)
```

Display an array as a matrix in a new figure window.

The origin is set at the upper left hand corner and rows (first dimension of the array) are displayed horizontally. The aspect ratio of the figure window is that of the array, unless this would make an excessively short or narrow figure.

Tick labels for the xaxis are placed on top.

With the exception of `fignum`, keyword arguments are passed to `imshow()`. You may set the `origin` kwarg to “lower” if you want the first row in the array to be at the bottom instead of the top.

`fignum: [ None | integer | False ]` By default, `matshow()` creates a new figure window with automatic numbering. If `fignum` is given as an integer, the created figure will use this figure number. Because of how `matshow()` tries to set the figure aspect ratio to be the one of the array, if you provide the number of an already existing figure, strange things may happen.

If `fignum` is `False` or `0`, a new figure window will **NOT** be created.

```python
matplotlib.pyplot.minorticks_off()
```

Remove minor ticks from the current plot.

```python
matplotlib.pyplot.minorticks_on()
```

Display minor ticks on the current plot.

Displaying minor ticks reduces performance; turn them off using `minorticks_off()` if drawing speed is a problem.

```python
matplotlib.pyplot.nipy_spectral()
```

set the default colormap to nipy_spectral and apply to current image if any. See help(colormaps) for more information

```python
matplotlib.pyplot.over(func, *args, **kwargs)
```

Deprecated since version 2.0: pyplot.hold is deprecated. Future behavior will be consistent with the long-time default: plot commands add elements without first clearing the Axes and/or Figure.

Call a function with `hold(True)`.

Calls:

```python
func(*args, **kwargs)
```

with `hold(True)` and then restores the hold state.

```python
matplotlib.pyplot.pause(interval)
```

Pause for `interval` seconds.

If there is an active figure it will be updated and displayed, and the GUI event loop will run during the pause.

If there is no active figure, or if a non-interactive backend is in use, this executes `time.sleep(interval)`.

This can be used for crude animation. For more complex animation, see `matplotlib.animation`.
This function is experimental; its behavior may be changed or extended in a future release.

```python
import matplotlib.pyplot as plt

plt.pcolor(*args, **kwargs)
```

Create a pseudocolor plot of a 2-D array.

**Note:** pcolor can be very slow for large arrays; consider using the similar but much faster `pcolormesh()` instead.

**Call signatures:**

```
pcolor(C, **kwargs)
pcolor(X, Y, C, **kwargs)
```

*C* is the array of color values.

*X* and *Y*, if given, specify the (x, y) coordinates of the colored quadrilaterals; the quadrilateral for \(C[i,j]\) has corners at:

\[
(X[i, j], Y[i, j]),
(X[i, j+1], Y[i, j+1]),
(X[i+1, j], Y[i+1, j]),
(X[i+1, j+1], Y[i+1, j+1]).
\]

Ideally the dimensions of *X* and *Y* should be one greater than those of *C*; if the dimensions are the same, then the last row and column of *C* will be ignored.

Note that the column index corresponds to the x-coordinate, and the row index corresponds to y; for details, see the Grid Orientation section below.

If either or both of *X* and *Y* are 1-D arrays or column vectors, they will be expanded as needed into the appropriate 2-D arrays, making a rectangular grid.

*X*, *Y* and *C* may be masked arrays. If either *C*[i, j], or one of the vertices surrounding *C*[i,j] (*X* or *Y* at [i, j], [i, j+1],[i, j],[i+1, j+1]) is masked, nothing is plotted.

**Keyword arguments:**

- **`cmap`**: [None | Colormap] A `matplotlib.colors.Colormap` instance. If None, use rc settings.
- **`norm`**: [None | Normalize] An `matplotlib.colors.Normalize` instance is used to scale luminance data to 0,1. If None, defaults to `normalize()`.
- **`vmin/vmax`**: [None | scalar] *vmin* and *vmax* are used in conjunction with `norm` to normalize luminance data. If either is None, it is autoscaled to the respective min or max of the color array *C*. If not None, *vmin* or *vmax* passed in here override any pre-existing values supplied in the `norm` instance.
- **`shading`**: [‘flat’ | ‘faceted’] If ‘faceted’, a black grid is drawn around each rectangle; if ‘flat’, edges are not drawn. Default is ‘flat’, contrary to MATLAB.

This kwarg is deprecated; please use ‘edgecolors’ instead:

- `shading='flat'` – `edgecolors='none'`
- shading='faceted' - edgecolors='k'

**edgecolors:** [None | 'none' | color | color sequence] If None, the rc setting is used by default.

If 'none', edges will not be visible.

An mpl color or sequence of colors will set the edge color

**alpha:** 0 <= scalar <= 1 or None the alpha blending value

**snap:** bool Whether to snap the mesh to pixel boundaries.

Return value is a `matplotlib.collections.Collection` instance. The grid orientation follows the MATLAB convention: an array C with shape (nrows, ncolumns) is plotted with the column number as X and the row number as Y, increasing up; hence it is plotted the way the array would be printed, except that the Y axis is reversed. That is, C is taken as C*([y, x]).

Similarly for `meshgrid()`:

```python
x = np.arange(5)
y = np.arange(3)
X, Y = np.meshgrid(x, y)
```

is equivalent to:

```python
X = array([[0, 1, 2, 3, 4],
           [0, 1, 2, 3, 4],
           [0, 1, 2, 3, 4]])
Y = array([[0, 0, 0, 0, 0],
           [1, 1, 1, 1, 1],
           [2, 2, 2, 2, 2]])
```

so if you have:

```python
C = rand(len(x), len(y))
```

then you need to transpose C:

```python
pcolor(X, Y, C.T)
```

or:

```python
pcolor(C.T)
```

MATLAB `pcolor()` always discards the last row and column of C, but matplotlib displays the last row and column if X and Y are not specified, or if X and Y have one more row and column than C.

kwargs can be used to control the `PolyCollection` properties:

</tbody>
</table>

**Note:** The default antialiaseds is False if the default edgecolors* = ”none” is used. This eliminates artificial lines at patch boundaries, and works regardless of the value of alpha. If *edgecolors is not “none”, then the default antialiaseds is taken from rcParams[‘patch.antialiased’], which defaults to True. Stroking the edges may be preferred if alpha is 1, but will cause artifacts otherwise.

See also:
**pcolormesh()** For an explanation of the differences between pcolor and pcolormesh.

**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

- All positional and all keyword arguments.

```python
matplotlib.pyplot.pcolormesh(*args, **kwargs)
```

Plot a quadrilateral mesh.

Call signatures:

```python
pcolormesh(C)
pcolormesh(X, Y, C)
pcolormesh(C, **kwargs)
```

Create a pseudocolor plot of a 2-D array.

`pcolormesh` is similar to `pcolor()`, but uses a different mechanism and returns a different object; `pcolor` returns a `PolyCollection` but `pcolormesh` returns a `QuadMesh`. It is much faster, so it is almost always preferred for large arrays.

`C` may be a masked array, but `X` and `Y` may not. Masked array support is implemented via `cmap` and `norm`; in contrast, `pcolor()` simply does not draw quadrilaterals with masked colors or vertices.

Keyword arguments:

- **`cmap`**: [None | `Colormap`] A `matplotlib.colors.Colormap` instance. If `None`, use rc settings.
- **`norm`**: [None | `Normalize`] A `matplotlib.colors.Normalize` instance is used to scale luminance data to 0,1. If `None`, defaults to `normalize()`.
- **`vmin`/**`vmax`**: [None | scalar] `vmin` and `vmax` are used in conjunction with `norm` to normalize luminance data. If either is `None`, it is autoscaled to the respective min or max of the color array `C`. If not `None`, `vmin` or `vmax` passed in here override any pre-existing values supplied in the `norm` instance.
- **`shading`**: ['flat' | 'gouraud'] 'flat' indicates a solid color for each quad. When 'gouraud', each quad will be Gouraud shaded. When gouraud shading, edgecolors is ignored.
- **`edgecolors`**: [None | 'None' | 'face' | color | color sequence] If `None`, the rc setting is used by default.
- **`alpha`**: $0 \leq \text{scalar} \leq 1$ or `None` the alpha blending value
Return value is a `matplotlib.collections.QuadMesh` object.

kwargs can be used to control the `matplotlib.collections.QuadMesh` properties:

See also:

`pcolor()` For an explanation of the grid orientation (Grid Orientation) and the expansion of 1-D X and/or Y to 2-D arrays.
Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[arg]:

- All positional and all keyword arguments.

```
matplotlib.pyplot.phase_spectrum(x, Fs=None, Fc=None, window=None, pad_to=None,
                                sides=None, hold=None, data=None, **kwargs)
```

Plot the phase spectrum.

Call signature:
```
phase_spectrum(x, Fs=2, Fc=0, window=mlab.window_hanning,
               pad_to=None, sides='default', **kwargs)
```

Compute the phase spectrum (unwrapped angle spectrum) of \( x \). Data is padded to a length of \( \text{pad\_to} \) and the windowing function \( \text{window} \) is applied to the signal.

**Parameters**

\textbf{x}: 1-D array or sequence

Array or sequence containing the data

\textbf{Fs}: scalar

The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, \( \text{freqs} \), in cycles per time unit. The default value is 2.

\textbf{window}: callable or ndarray

A function or a vector of length \( \text{NFFT} \). To create window vectors see \( \text{window\_hanning()} \), \( \text{window\_none()} \), \( \text{numpy\_blackman()} \), \( \text{numpy\_hamming()} \), \( \text{numpy\_bartlett()} \), \( \text{scipy\_signal()} \), \( \text{scipy\_signal\_get\_window()} \), etc. The default is \( \text{window\_hanning()} \). If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.

\textbf{sides}: [‘default’ | ‘onesided’ | ‘twosided’]

Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.

\textbf{pad\_to}: integer

The number of points to which the data segment is padded when performing the FFT. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the \( n \) parameter in the call to \( \text{fft()} \). The default is None, which sets \( \text{pad\_to} \) equal to the length of the input signal (i.e. no padding).

\textbf{Fc}: integer
The center frequency of $x$ (defaults to 0), which offsets the x extents of the plot to reflect the frequency range used when a signal is acquired and then filtered and downsampled to baseband.

**kwargs:

Returns spectrum : 1-D array

    The values for the phase spectrum in radians (real valued)

freqs : 1-D array

    The frequencies corresponding to the elements in spectrum

line : a Line2D instance

    The line created by this function

See also:

magnitude_spectrum() magnitude_spectrum() plots the magnitudes of the corresponding frequencies.

angle_spectrum() angle_spectrum() plots the wrapped version of this function.

specgram() specgram() can plot the phase spectrum of segments within the signal in a colormap.

In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]: * All arguments with the following names: ‘x’.
matplotlib.pyplot.pie(x, explode=None, labels=None, colors=None, autopct=None, pctdistance=0.6, shadow=False, labeldistance=1.1, startangle=None, radius=None, counterclock=True, wedgeprops=None, textprops=None, center=(0, 0), frame=False, hold=None, data=None)

Plot a pie chart.

Make a pie chart of array x. The fractional area of each wedge is given by x/sum(x). If sum(x) <= 1, then the values of x give the fractional area directly and the array will not be normalized. The wedges are plotted counterclockwise, by default starting from the x-axis.

Keyword arguments:

**explode:** [None | len(x) sequence] If not None, is a len(x) array which specifies the fraction of the radius with which to offset each wedge.

**colors:** [None | color sequence] A sequence of matplotlib color args through which the pie chart will cycle. If None, will use the colors in the currently active cycle.

**labels:** [None | len(x) sequence of strings] A sequence of strings providing the labels for each wedge

**autopct:** [None | format string | format function] If not None, is a string or function used to label the wedges with their numeric value. The label will be placed inside
the wedge. If it is a format string, the label will be \texttt{fmt\%pct}. If it is a function, it will be called.

\texttt{pctdistance: scalar} The ratio between the center of each pie slice and the start of the text generated by \texttt{autopct}. Ignored if \texttt{autopct} is \texttt{None}; default is 0.6.

\texttt{labeldistance: scalar} The radial distance at which the pie labels are drawn

\texttt{shadow: [ False | True ]} Draw a shadow beneath the pie.

\texttt{startangle: [ None | Offset angle ]} If not \texttt{None}, rotates the start of the pie chart by \texttt{angle} degrees counterclockwise from the x-axis.

\texttt{radius: [ None | scalar ]} The radius of the pie, if \texttt{radius} is \texttt{None} it will be set to 1.

\texttt{counterclock: [ False | True ]} Specify fractions direction, clockwise or counterclockwise.

\texttt{wedgeprops: [ None | dict of key value pairs ]} Dict of arguments passed to the wedge objects making the pie. For example, you can pass in \texttt{wedgeprops = \{ ‘linewidth’ : 3 \}} to set the width of the wedge border lines equal to 3. For more details, look at the doc/arguments of the wedge object. By default \texttt{clip_on=False}.

\texttt{textprops: [ None | dict of key value pairs ]} Dict of arguments to pass to the text objects.

\texttt{center: [ (0,0) | sequence of 2 scalars ]} Center position of the chart.

\texttt{frame: [ False | True ]} Plot axes frame with the chart.

The pie chart will probably look best if the figure and axes are square, or the Axes aspect is equal.

\texttt{e.g.:}

\begin{verbatim}
figure(figsize=(8,8))
ax = axes([0.1, 0.1, 0.8, 0.8])
\end{verbatim}

or:

\begin{verbatim}
axes(aspect=1)
\end{verbatim}

\textbf{Return value:} If \texttt{autopct} is \texttt{None}, return the tuple (\texttt{patches, texts}):  
- \texttt{patches} is a sequence of \texttt{matplotlib.patches.Wedge} instances  
- \texttt{texts} is a list of the label \texttt{matplotlib.text.Text} instances.

If \texttt{autopct} is not \texttt{None}, return the tuple (\texttt{patches, texts, autotexts}), where \texttt{patches} and \texttt{texts} are as above, and \texttt{autotexts} is a list of \texttt{Text} instances for the numeric labels.

\textbf{Note:} In addition to the above described arguments, this function can take a \texttt{data} keyword argument. If such a \texttt{data} argument is given, the following arguments are replaced by \texttt{data[<arg>]}:  
- All arguments with the following names: ‘colors’, ‘explode’, ‘labels’, ‘x’.
**matplotlib.pyplot.pink()**

Set the default colormap to pink and apply to current image if any. See help(colormaps) for more information.

**matplotlib.pyplot.plasma()**

Set the default colormap to plasma and apply to current image if any. See help(colormaps) for more information.

**matplotlib.pyplot.plot(*args, **kwargs)**

Plot lines and/or markers to the Axes. *args* is a variable length argument, allowing for multiple x, y pairs with an optional format string. For example, each of the following is legal:

```python
plot(x, y)  # plot x and y using default line style and color
plot(x, y, 'bo')  # plot x and y using blue circle markers
plot(y)  # plot y using x as index array 0..N-1
plot(y, 'r+')  # ditto, but with red plusses
```

If x and/or y is 2-dimensional, then the corresponding columns will be plotted.

If used with labeled data, make sure that the color spec is not included as an element in data, as otherwise the last case `plot("v","r", data={"v":..., "r":...})` can be interpreted as the first case which would do `plot(v, r)` using the default line style and color.

If not used with labeled data (i.e., without a data argument), an arbitrary number of x, y, fmt groups can be specified, as in:

```python
a.plot(x1, y1, 'g^', x2, y2, 'g-')
```

Return value is a list of lines that were added.

By default, each line is assigned a different style specified by a ‘style cycle’. To change this behavior, you can edit the axes.prop_cycle rcParam.

The following format string characters are accepted to control the line style or marker:
<table>
<thead>
<tr>
<th>character</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'-'</td>
<td>solid line style</td>
</tr>
<tr>
<td>'--'</td>
<td>dashed line style</td>
</tr>
<tr>
<td>'-.'</td>
<td>dash-dot line style</td>
</tr>
<tr>
<td>':'</td>
<td>dotted line style</td>
</tr>
<tr>
<td>','</td>
<td>point marker</td>
</tr>
<tr>
<td>'o'</td>
<td>circle marker</td>
</tr>
<tr>
<td>'v'</td>
<td>triangle_down marker</td>
</tr>
<tr>
<td>'^'</td>
<td>triangle_up marker</td>
</tr>
<tr>
<td>'&lt;'</td>
<td>triangle_left marker</td>
</tr>
<tr>
<td>'&gt;'</td>
<td>triangle_right marker</td>
</tr>
<tr>
<td>'1'</td>
<td>tri_down marker</td>
</tr>
<tr>
<td>'2'</td>
<td>tri_up marker</td>
</tr>
<tr>
<td>'3'</td>
<td>tri_left marker</td>
</tr>
<tr>
<td>'4'</td>
<td>tri_right marker</td>
</tr>
<tr>
<td>'s'</td>
<td>square marker</td>
</tr>
<tr>
<td>'p'</td>
<td>pentagon marker</td>
</tr>
<tr>
<td>'*'</td>
<td>star marker</td>
</tr>
<tr>
<td>'h'</td>
<td>hexagon1 marker</td>
</tr>
<tr>
<td>'H'</td>
<td>hexagon2 marker</td>
</tr>
<tr>
<td>'+'</td>
<td>plus marker</td>
</tr>
<tr>
<td>'x'</td>
<td>x marker</td>
</tr>
<tr>
<td>'D'</td>
<td>diamond marker</td>
</tr>
<tr>
<td>'d'</td>
<td>thin_diamond marker</td>
</tr>
<tr>
<td>'</td>
<td>'</td>
</tr>
<tr>
<td>'_'</td>
<td>hline marker</td>
</tr>
</tbody>
</table>

The following color abbreviations are supported:

<table>
<thead>
<tr>
<th>character</th>
<th>color</th>
</tr>
</thead>
<tbody>
<tr>
<td>'b'</td>
<td>blue</td>
</tr>
<tr>
<td>'g'</td>
<td>green</td>
</tr>
<tr>
<td>'r'</td>
<td>red</td>
</tr>
<tr>
<td>'c'</td>
<td>cyan</td>
</tr>
<tr>
<td>'m'</td>
<td>magenta</td>
</tr>
<tr>
<td>'y'</td>
<td>yellow</td>
</tr>
<tr>
<td>'k'</td>
<td>black</td>
</tr>
<tr>
<td>'w'</td>
<td>white</td>
</tr>
</tbody>
</table>

In addition, you can specify colors in many weird and wonderful ways, including full names ('green'), hex strings ('#008000'), RGB or RGBA tuples ((0, 1, 0, 1)) or grayscale intensities as a string ('0.8'). Of these, the string specifications can be used in place of a fmt group, but the tuple forms can be used only as kwargs.

Line styles and colors are combined in a single format string, as in 'bo' for blue circles.

The kwargs can be used to set line properties (any property that has a set_* method). You can use this to set a line label (for auto legends), linewidth, anitialising, marker face color, etc. Here is an
example:

```python
plot([1,2,3], [1,2,3], 'go-', label='line 1', linewidth=2)
plot([1,2,3], [1,4,9], 'rs', label='line 2')
axis([0, 4, 0, 10])
legend()
```

If you make multiple lines with one plot command, the kwargs apply to all those lines, e.g.:

```python
plot(x1, y1, x2, y2, antialiased=False)
```

Neither line will be antialiased.

You do not need to use format strings, which are just abbreviations. All of the line properties can be controlled by keyword arguments. For example, you can set the color, marker, linestyle, and markerfacecolor with:

```python
plot(x, y, color='green', linestyle='dashed', marker='o',
     markerfacecolor='blue', markersize=12).
```

See `Line2D` for details.

The kwargs are `Line2D` properties:

</tbody>
</table>

kwarg's scalex and scaley, if defined, are passed on to autoscale_view() to determine whether the x and y axes are autoscaled; the default is True.

**Note:** In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: ‘x’, ‘y’.

matplotlib.pyplot.plot_date(x, y, fmt='o', tz=None, xdate=True, ydate=False, hold=None, data=None, **kwargs)

A plot with data that contains dates.

Similar to the plot() command, except the x or y (or both) data is considered to be dates, and the axis is labeled accordingly.

x and/or y can be a sequence of dates represented as float days since 0001-01-01 UTC.

Note if you are using custom date tickers and formatters, it may be necessary to set the format/locators after the call to method:plot_date since method:plot_date will set the default tick locator to class:matplotlib.dates.AutoDateLocator (if the tick locator is not already set to a class:matplotlib.dates.DateLocator instance) and the default tick formatter to class:matplotlib.dates.AutoDateFormatter (if the tick formatter is not already set to a class:matplotlib.dates.DateFormatter instance).

**Parameters fmt**: string
The plot format string.

**tz**: [None | timezone string | tzinfo instance]

The time zone to use in labeling dates. If None, defaults to rc value.

**xdate**: boolean

If True, the x-axis will be labeled with dates.

**ydate**: boolean

If True, the y-axis will be labeled with dates.

**Returns**: lines

**Other Parameters**: kwargs : matplotlib.lines.Line2D

**properties**:

.. note::

In addition to the above described arguments, this function can take a **data** keyword argument. If such a **data** argument is given, the following arguments are replaced by **data[<arg>]**:

- All arguments with the following names: ‘x’, ‘y’.

See also:

- `matplotlib.dates` helper functions on dates
- `matplotlib.dates.date2num` how to convert dates to num
- `matplotlib.dates.num2date` how to convert num to dates
- `matplotlib.dates.drange` how floating point dates

`matplotlib.pyplot.plotfile(fname, cols=(0, ), plotfuncs=None, comments='#', skiprows=0, checkrows=5, delimiter=' ', names=None, subplots=True, newfig=True, **kwargs)`

Plot the data in a file.

- `cols` is a sequence of column identifiers to plot. An identifier is either an int or a string. If it is an int, it indicates the column number. If it is a string, it indicates the column header. `matplotlib` will make column headers lower case, replace spaces with underscores, and remove all illegal characters; so 'Adj Close*' will have name 'adj_close'.
  
  - If `len(cols) == 1`, only that column will be plotted on the y axis.
  
  - If `len(cols) > 1`, the first element will be an identifier for data for the x axis and the remaining elements will be the column indexes for multiple subplots if `subplots` is `True` (the default), or for lines in a single subplot if `subplots` is `False`.  

---

44.1. `matplotlib.pyplot` 1505
plotfuncs, if not None, is a dictionary mapping identifier to an Axes plotting function as a string. Default is 'plot', other choices are 'semilogy', 'fill', 'bar', etc. You must use the same type of identifier in the cols vector as you use in the plotfuncs dictionary, e.g., integer column numbers in both or column names in both. If subplots is False, then including any function such as 'semilogy' that changes the axis scaling will set the scaling for all columns.

comments, skiprows, checkrows, delimiter, and names are all passed on to matplotlib.pylab.csv2rec() to load the data into a record array.

If newfig is True, the plot always will be made in a new figure; if False, it will be made in the current figure if one exists, else in a new figure.

kwargs are passed on to plotting functions.

Example usage:

```python
# plot the 2nd and 4th column against the 1st in two subplots
plotfile(fname, (0,1,3))

# plot using column names; specify an alternate plot type for volume
plotfile(fname, ('date', 'volume', 'adj_close'),
         plotfuncs={'volume': 'semilogy'})
```

Note: plotfile is intended as a convenience for quickly plotting data from flat files; it is not intended as an alternative interface to general plotting with pyplot or matplotlib.

matplotlib.pyplot.polar(*args, **kwargs)
Make a polar plot.

call signature:

```python
polar(theta, r, **kwargs)
```

Multiple theta, r arguments are supported, with format strings, as in plot().

matplotlib.pyplot.prism()
set the default colormap to prism and apply to current image if any. See help(colormaps) for more information

matplotlib.pyplot.psd(x, NFFT=None, Fs=2, Fc=0, detrend=mlab.detrend_none, window=mlab.window_hanning, noverlap=0, pad_to=None, sides='default', scale_by_freq=None, return_line=None, hold=None, data=None, **kwags)
Plot the power spectral density.

call signature:

```python
psd(x, NFFT=256, Fs=2, Fc=0, detrend=mlab.detrend_none,
    window=mlab.window_hanning, noverlap=0, pad_to=None,
    sides='default', scale_by_freq=None, return_line=None, **kwargs)
```

The power spectral density $P_{xx}$ by Welch’s average periodogram method. The vector $x$ is divided into NFFT length segments. Each segment is detrended by function detrend and windowed by function window. noverlap gives the length of the overlap between segments. The $|f(i)|^2$ of each segment $i$ are averaged to compute $P_{xx}$, with a scaling to correct for power loss due to windowing.
If $\text{len}(x) < \text{NFFT}$, it will be zero padded to $\text{NFFT}$.

**Parameters**

- **x**: 1-D array or sequence
  
  Array or sequence containing the data

- **Fs**: scalar
  
  The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, freqs, in cycles per time unit. The default value is 2.

- **window**: callable or ndarray
  
  A function or a vector of length $\text{NFFT}$. To create window vectors see `window_hanning()`, `window_none()`, `numpy.blackman()`, `numpy.hamming()`, `numpy.bartlett()`, `scipy.signal()`, etc. The default is `window_hanning()`. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.

- **sides**: [‘default’ | ‘onesided’ | ‘twosided’]
  
  Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.

- **pad_to**: integer
  
  The number of points to which the data segment is padded when performing the FFT. This can be different from $\text{NFFT}$, which specifies the number of data points used. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the $n$ parameter in the call to `fft()`. The default is None, which sets `pad_to` equal to $\text{NFFT}$

- **NFFT**: integer
  
  The number of data points used in each block for the FFT. A power 2 is most efficient. The default value is 256. This should *NOT* be used to get zero padding, or the scaling of the result will be incorrect. Use `pad_to` for this instead.

- **detrend**: {‘default’, ‘constant’, ‘mean’, ‘linear’, ‘none’} or callable
  
  The function applied to each segment before fft-ing, designed to remove the mean or linear trend. Unlike in MATLAB, where the `detrend` parameter is a vector, in matplotlib is it a function. The `pylab` module defines `detrend_none()`, `detrend_mean()`, and `detrend_linear()`, but you can use a custom function as well. You can also use a string to choose one of the functions. ‘default’, ‘constant’, and ‘mean’ call `detrend_mean()`. ‘linear’ calls `detrend_linear()`. ‘none’ calls `detrend_none()`.

- **scale_by_freq**: boolean, optional
Specifies whether the resulting density values should be scaled by the scaling frequency, which gives density in units of Hz^-1. This allows for integration over the returned frequency values. The default is True for MATLAB compatibility.

**nooverlap**: integer

The number of points of overlap between segments. The default value is 0 (no overlap).

**Fc**: integer

The center frequency of x (defaults to 0), which offsets the x extents of the plot to reflect the frequency range used when a signal is acquired and then filtered and downsampled to baseband.

**return_line**: bool

Whether to include the line object plotted in the returned values. Default is False.

**kwargs**:

Keyword arguments control the Line2D properties:

**Returns** $P_{xx}$ : 1-D array

The values for the power spectrum $P_{xx}$ before scaling (real valued)

$freqs$ : 1-D array

The frequencies corresponding to the elements in $P_{xx}$

*line* : a Line2D instance

The line created by this function. Only returned if return_line is True.

See also:

specgram() specgram() differs in the default overlap; in not returning the mean of the segment periodograms; in returning the times of the segments; and in plotting a colormap instead of a line.

magnitude_spectrum() magnitude_spectrum() plots the magnitude spectrum.

csd() csd() plots the spectral density between two signals.

In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]: * All arguments with the following names: ‘x’.

**Notes**

For plotting, the power is plotted as $10 \log_{10}(P_{xx})$ for decibels, though $P_{xx}$ itself is returned.
References

Examples

```python
import matplotlib.pyplot as plt

# Sample data
frequency = [0, 10, 20, 30, 40, 50]
power_spectral_density = [94, 84, 74, 64, 54, 44, 34, 24, 14]

# Plot
fig, ax1 = plt.subplots()
ax1.plot(frequency, power_spectral_density, label='Power Spectral Density (dB/Hz)')
ax1.set_ylabel('Power Spectral Density (dB/Hz)')
ax1.set_xlabel('Frequency')

ax2 = ax1.twinx()
ax2.quiver(frequency, power_spectral_density, [0.1]*len(frequency), [0.0]*len(frequency), color='blue', pivot='tail', width=0.01, headwidth=3, headlength=4, alpha=0.7)
ax2.set_ylabel('Quiver arrows')

plt.title('Sample quiver plot')
plt.legend()
plt.show()
```

**matplotlib.pyplot.quiver(args, **kw)**

Plot a 2-D field of arrows.

Call signatures:

- `quiver(U, V, **kw)`
- `quiver(U, V, C, **kw)`
- `quiver(X, Y, U, V, **kw)`
- `quiver(X, Y, U, V, C, **kw)`

Arguments:

- `X, Y`: The x and y coordinates of the arrow locations (default is tail of arrow; see `pivot` kwarg)
- `U, V`: Give the x and y components of the arrow vectors
- `C`: An optional array used to map colors to the arrows
All arguments may be 1-D or 2-D arrays or sequences. If \( X \) and \( Y \) are absent, they will be generated as a uniform grid. If \( U \) and \( V \) are 2-D arrays but \( X \) and \( Y \) are 1-D, and if \text{len}(X)\text{and} \text{len}(Y) \) match the column and row dimensions of \( U \), then \( X \) and \( Y \) will be expanded with \text{numpy.meshgrid}().

\( U, V, C \) may be masked arrays, but masked \( X, Y \) are not supported at present.

Keyword arguments:

- **units**: [‘width’ | ‘height’ | ‘dots’ | ‘inches’ | ‘x’ | ‘y’ | ‘xy’] Arrow units; the arrow dimensions except for length are in multiples of this unit.
  - ‘width’ or ‘height’: the width or height of the axes
  - ‘dots’ or ‘inches’: pixels or inches, based on the figure dpi
  - ‘x’, ‘y’, or ‘xy’: \( X, Y, \text{or} \sqrt{X^2+Y^2} \) data units

The arrows scale differently depending on the units. For ‘x’ or ‘y’, the arrows get larger as one zooms in; for other units, the arrow size is independent of the zoom state. For ‘width or ‘height’, the arrow size increases with the width and height of the axes, respectively, when the window is resized; for ‘dots’ or ‘inches’, resizing does not change the arrows.

- **angles**: [‘uv’ | ‘xy’ | array] With the default ‘uv’, the arrow axis aspect ratio is 1, so that if \( U*V \) the orientation of the arrow on the plot is 45 degrees CCW from the horizontal axis (positive to the right). With ‘xy’, the arrow points from \( (x,y) \) to \( (x+u, y+v) \). Use this for plotting a gradient field, for example. Alternatively, arbitrary angles may be specified as an array of values in degrees, CCW from the horizontal axis. Note: inverting a data axis will correspondingly invert the arrows only with \text{angles=’xy’}.

- **scale**: [None | float] Data units per arrow length unit, e.g., m/s per plot width; a smaller scale parameter makes the arrow longer. If None, a simple autoscaling algorithm is used, based on the average vector length and the number of vectors. The arrow length unit is given by the \text{scale_units} parameter

- **scale_units**: None, or any of the units options. For example, if \text{scale_units} is ‘inches’, \text{scale} is 2.0, and \( (u,v) = (1,0) \), then the vector will be 0.5 inches long. If \text{scale_units} is ‘width’, then the vector will be half the width of the axes.

If \text{scale_units} is ‘x’ then the vector will be 0.5 x-axis units. To plot vectors in the x-y plane, with \( u \) and \( v \) having the same units as \( x \) and \( y \), use “\text{angles=’xy’}, \text{scale_units=’xy’}, \text{scale=1}”.

- **width**: Shaft width in arrow units; default depends on choice of units, above, and number of vectors; a typical starting value is about 0.005 times the width of the plot.

- **headwidth**: scalar Head width as multiple of shaft width, default is 3

- **headlength**: scalar Head length as multiple of shaft width, default is 5

- **headaxislength**: scalar Head length at shaft intersection, default is 4.5

- **minshaft**: scalar Length below which arrow scales, in units of head length. Do not set this to less than 1, or small arrows will look terrible! Default is 1
**minlength**: scalar Minimum length as a multiple of shaft width; if an arrow length is less than this, plot a dot (hexagon) of this diameter instead. Default is 1.

**pivot**: [‘tail’ | ‘mid’ | ‘middle’ | ‘tip’ ] The part of the arrow that is at the grid point; the arrow rotates about this point, hence the name pivot.

**color**: [color | color sequence ] This is a synonym for the PolyCollection facecolor kwarg. If C has been set, color has no effect.

The defaults give a slightly swept-back arrow; to make the head a triangle, make headaxislength the same as headlength. To make the arrow more pointed, reduce headwidth or increase headlength and headaxislength. To make the head smaller relative to the shaft, scale down all the head parameters. You will probably do best to leave minshaft alone.

linewidths and edgecolors can be used to customize the arrow outlines. Additional PolyCollection keyword arguments:

```python
matplotlib.pyplot.quiverkey(*args, **kw)
```

Add a key to a quiver plot.

Call signature:

```python
quiverkey(Q, X, Y, U, label, **kw)
```

Arguments:

- **Q**: The Quiver instance returned by a call to quiver.
- **X, Y**: The location of the key; additional explanation follows.
- **U**: The length of the key
- **label**: A string with the length and units of the key

Keyword arguments:

- **coordinates** = [‘axes’ | ‘figure’ | ‘data’ | ‘inches’ ] Coordinate system and units for X, Y: ‘axes’ and ‘figure’ are normalized coordinate systems with 0,0 in the lower left and 1,1 in the upper right; ‘data’ are the axes data coordinates (used for the locations of the vectors in the quiver plot itself); ‘inches’ is position in the figure in inches, with 0,0 at the lower left corner.
- **color**: overrides face and edge colors from Q.
- **labelpos** = [‘N’ | ‘S’ | ‘E’ | ‘W’ ] Position the label above, below, to the right, to the left of the arrow, respectively.
- **labelsep**: Distance in inches between the arrow and the label. Default is 0.1
- **labelcolor**: defaults to default Text color.
- **fontproperties**: A dictionary with keyword arguments accepted by the FontProperties initializer: family, style, variant, size, weight

Any additional keyword arguments are used to override vector properties taken from Q.

The positioning of the key depends on X, Y, coordinates, and labelpos. If labelpos is ‘N’ or ‘S’, X, Y give the position of the middle of the key arrow. If labelpos is ‘E’, X, Y positions the head, and if labelpos is ‘W’, X, Y positions the tail; in either of these two cases, X, Y is somewhere in the middle of the arrow+label key object.
matplotlib.pyplot.rc(*args, **kwargs)

Set the current rc params. Group is the grouping for the rc, e.g., for `lines.linewidth` the group is `lines`, for `axes.facecolor`, the group is `axes`, and so on. Group may also be a list or tuple of group names, e.g., `(xtick, ytick)`. `kwargs` is a dictionary attribute name/value pairs, e.g.:

```python
rc('lines', linewidth=2, color='r')
```

sets the current rc params and is equivalent to:

```python
rcParams['lines.linewidth'] = 2
rcParams['lines.color'] = 'r'
```

The following aliases are available to save typing for interactive users:

<table>
<thead>
<tr>
<th>Alias</th>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>'lw'</td>
<td>'linewidth'</td>
</tr>
<tr>
<td>'ls'</td>
<td>'linestyle'</td>
</tr>
<tr>
<td>'c'</td>
<td>'color'</td>
</tr>
<tr>
<td>'fc'</td>
<td>'facecolor'</td>
</tr>
<tr>
<td>'ec'</td>
<td>'edgecolor'</td>
</tr>
<tr>
<td>'mew'</td>
<td>'markeredgewidth'</td>
</tr>
<tr>
<td>'aa'</td>
<td>'antialiased'</td>
</tr>
</tbody>
</table>

Thus you could abbreviate the above rc command as:

```python
rc('lines', lw=2, c='r')
```

Note you can use python’s `kwargs` dictionary facility to store dictionaries of default parameters. e.g., you can customize the font rc as follows:

```python
font = {'family': 'monospace',
        'weight': 'bold',
        'size': 'larger'}
rc('font', **font)  # pass in the font dict as kwargs
```

This enables you to easily switch between several configurations. Use `rcdefaults()` to restore the default rc params after changes.

matplotlib.pyplot.rc_context(rc=None, fname=None)

Return a context manager for managing rc settings.

This allows one to do:

```python
with mpl.rc_context(fname='screen.rc'):
    plt.plot(x, a)
with mpl.rc_context(fname='print.rc'):
    plt.plot(x, b)
plt.plot(x, c)
```

The ‘a’ vs ‘x’ and ‘c’ vs ‘x’ plots would have settings from ‘screen.rc’, while the ‘b’ vs ‘x’ plot would have settings from ‘print.rc’.
A dictionary can also be passed to the context manager:

```python
with mpl.rc_context(rc={'text.usetex': True}, fname='screen.rc'):
    plt.plot(x, a)
```

The ‘rc’ dictionary takes precedence over the settings loaded from ‘fname’. Passing a dictionary only is also valid.

**matplotlib.pyplot.rcdefaults()**

Restore the default rc params. These are not the params loaded by the rc file, but mpl’s internal params. See rc_file_defaults for reloading the default params from the rc file.

**matplotlib.pyplot.rgrids(*args, **kwargs)**

Get or set the radial gridlines on a polar plot.

Call signatures:

```python
lines, labels = rgrids()
lines, labels = rgrids(radii, labels=None, angle=22.5, **kwargs)
```

When called with no arguments, rgrid() simply returns the tuple `(lines, labels)`, where `lines` is an array of radial gridlines (`Line2D` instances) and `labels` is an array of tick labels (`Text` instances). When called with arguments, the labels will appear at the specified radial distances and angles.

`labels`, if not `None`, is a `len(radii)` list of strings of the labels to use at each angle.

If `labels` is `None`, the rformatter will be used.

Examples:

```python
# set the locations of the radial gridlines and labels
lines, labels = rgrids( (0.25, 0.5, 1.0) )

# set the locations and labels of the radial gridlines and labels
lines, labels = rgrids( (0.25, 0.5, 1.0), ('Tom', 'Dick', 'Harry') )
```

**matplotlib.pyplot.savefig(*args, **kwargs)**

Save the current figure.

Call signature:

```python
savefig(fname, dpi=None, facecolor='w', edgecolor='w', orientation='portrait', papertype=None, format=None, transparent=False, bbox_inches=None, pad_inches=0.1, frameon=None)
```

The output formats available depend on the backend being used.

Arguments:

- **fname**: A string containing a path to a filename, or a Python file-like object, or possibly some backend-dependent object such as `PdfPages`.

  If `format` is `None` and `fname` is a string, the output format is deduced from the extension of the filename. If the filename has no extension, the value of the rc parameter
savefig.format is used.

If fname is not a string, remember to specify format to ensure that the correct backend is used.

Keyword arguments:

- **dpi**: [None | scalar > 0 | ‘figure’] The resolution in dots per inch. If None it will default to the value savefig.dpi in the matplotlibrc file. If ‘figure’ it will set the dpi to be the value of the figure.

- **facecolor, edgecolor**: the colors of the figure rectangle

- **orientation**: [‘landscape’ | ‘portrait’] not supported on all backends; currently only on postscript output

- **format**: One of the file extensions supported by the active backend. Most backends support png, pdf, ps, eps and svg.

- **transparent**: If True, the axes patches will all be transparent; the figure patch will also be transparent unless facecolor and/or edgecolor are specified via kwargs. This is useful, for example, for displaying a plot on top of a colored background on a web page. The transparency of these patches will be restored to their original values upon exit of this function.

- **frameon**: If True, the figure patch will be colored, if False, the figure background will be transparent. If not provided, the rcParam ‘savefig.frameon’ will be used.

- **bbox_inches**: Bbox in inches. Only the given portion of the figure is saved. If ‘tight’, try to figure out the tight bbox of the figure.

- **pad_inches**: Amount of padding around the figure when bbox_inches is ‘tight’.

- **bbox_extra_artists**: A list of extra artists that will be considered when the tight bbox is calculated.

```python
matplotlib.pyplot.sca(ax)
```

Set the current Axes instance to ax.

The current Figure is updated to the parent of ax.

```python
matplotlib.pyplot.scatter(x, y, s=None, c=None, marker=None, cmap=None, norm=None, vmin=None, vmax=None, alpha=None, linewidths=None, verts=None, edgecolors=None, hold=None, data=None, **kwargs)
```

Make a scatter plot of x vs y

Marker size is scaled by s and marker color is mapped to c

**Parameters**

- **x, y**: array_like, shape (n, )
  
  Input data

- **s**: scalar or array_like, shape (n, ), optional
size in points^2. Default is rcParams['lines.markersize'] ** 2.

c : color, sequence, or sequence of color, optional, default: ‘b’

c can be a single color format string, or a sequence of color specifications of length N, or a sequence of N numbers to be mapped to colors using the cmap and norm specified via kwargs (see below). Note that c should not be a single numeric RGB or RGBA sequence because that is indistinguishable from an array of values to be colormapped. c can be a 2-D array in which the rows are RGB or RGBA, however, including the case of a single row to specify the same color for all points.

marker : MarkerStyle, optional, default: ‘o’

See markers for more information on the different styles of markers scatter supports. marker can be either an instance of the class or the text shorthand for a particular marker.

cmap : Colormap, optional, default: None

A Colormap instance or registered name. cmap is only used if c is an array of floats. If None, defaults to rc image.cmap.

norm : Normalize, optional, default: None

A Normalize instance is used to scale luminance data to 0, 1. norm is only used if c is an array of floats. If None, use the default normalize().

vmin, vmax : scalar, optional, default: None

vmin and vmax are used in conjunction with norm to normalize luminance data. If either are None, the min and max of the color array is used. Note if you pass a norm instance, your settings for vmin and vmax will be ignored.

alpha : scalar, optional, default: None

The alpha blending value, between 0 (transparent) and 1 (opaque)

linewidths : scalar or array_like, optional, default: None

If None, defaults to (lines.linewidth,).

verts : sequence of (x, y), optional

If marker is None, these vertices will be used to construct the marker. The center of the marker is located at (0,0) in normalized units. The overall marker is rescaled by s.

dedgecolors : color or sequence of color, optional, default: None

If None, defaults to ‘face’

If ‘face’, the edge color will always be the same as the face color.

If it is ‘none’, the patch boundary will not be drawn.

For non-filled markers, the edgecolors kwarg is ignored and forced to ‘face’ internally.
Returns paths: \textit{PathCollection}

Other Parameters kwargs: \textit{Collection} properties

See also:

\textit{plot} to plot scatter plots when markers are identical in size and color

Notes

- The \textit{plot} function will be faster for scatterplots where markers don’t vary in size or color.
- Any or all of \textit{x}, \textit{y}, \textit{s}, and \textit{c} may be masked arrays, in which case all masks will be combined and only unmasked points will be plotted.

Fundamentally, scatter works with 1-D arrays; \textit{x}, \textit{y}, \textit{s}, and \textit{c} may be input as 2-D arrays, but within scatter they will be flattened. The exception is \textit{c}, which will be flattened only if its size matches the size of \textit{x} and \textit{y}.

Examples
**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

`matplotlib.pyplot.sci(im)`

Set the current image. This image will be the target of colormap commands like `jet()`, `hot()` or `clim()`). The current image is an attribute of the current axes.

`matplotlib.pyplot.semilogx(*args, **kwargs)`

Make a plot with log scaling on the x axis.

**Parameters**

- `base` : float, optional
  Base of the x logarithm. The scalar should be larger than 1.

- `subsx` : array_like, optional
  The location of the minor xticks; `None` defaults to autosubs, which depend on the number of decades in the plot; see `set_xscale()` for details.

- `nonposx` : string, optional, {'mask', 'clip'}
  Non-positive values in x can be masked as invalid, or clipped to a very small positive number.

**Returns**

- `plot` : Log-scaled plot on the x axis.

**Other Parameters**

- class:`'~matplotlib.lines.Line2D'` properties:

`loglog` For example code and figure.

Notes

This function supports all the keyword arguments of `plot()` and `matplotlib.axes.Axes.set_xscale()`.

`matplotlib.pyplot.semilogy(*args, **kwargs)`

Make a plot with log scaling on the y axis.

Parameters

`basey`: scalar > 1

Base of the y logarithm.

`subsy` [None or iterable] The location of the minor yticks. None defaults
to autosubs, which depend on the number of decades in the plot. See
\texttt{set_yscale()} for details.

\textbf{nonposy} [{\texttt{‘mask’} | \texttt{‘clip’}} str] Non-positive values in y can be masked as
invalid, or clipped to a very small positive number.

\textbf{Returns} \texttt{Line2D}

Line instance of the plot.

\textbf{Other Parameters} \texttt{kwargs} : \texttt{Line2D} properties,

\texttt{plot} and \texttt{matplotlib.axes.Axes.set_yscale} arguments.

See also:

*loglog()* For example code and figure.

```python
import matplotlib.pyplot as plt

matplotlib.pyplot.set_cmap(cmap)
```

Set the default colormap. Applies to the current image if any. See help(colormaps) for more information.

cmap must be a :class:`Colormap` instance, or the name of a registered colormap.

See matplotlib.cm.register_cmap() and matplotlib.cm.get_cmap().

```python
import matplotlib.pyplot as plt

matplotlib.pyplot.setp(*args, **kwargs)
```

Set a property on an artist object.

matplotlib supports the use of `setp()` (“set property”) and `getp()` to set and get object properties, as well as to do introspection on the object. For example, to set the linestyle of a line to be dashed, you can do:

```python
>>> line, = plt.plot([1,2,3])
>>> plt.setp(line, linestyle='--')
```

If you want to know the valid types of arguments, you can provide the name of the property you want to set without a value:

```python
>>> plt.setp(line, 'linestyle')
linestyle: [ '-' | '--' | '-' | ':' | 'steps' | 'None' ]
```

If you want to see all the properties that can be set, and their possible values, you can do:

```python
>>> plt.setp(line)
... long output listing omitted
```

*setp()* operates on a single instance or a list of instances. If you are in query mode introspecting the possible values, only the first instance in the sequence is used. When actually setting values, all the
instances will be set. e.g., suppose you have a list of two lines, the following will make both lines thicker and red:

```python
>>> x = arange(0,1.0,0.01)
>>> y1 = sin(2*pi*x)
>>> y2 = sin(4*pi*x)
>>> lines = plot(x, y1, x, y2)
>>> setp(lines, linewidth=2, color='r')
```

`setp()` works with the MATLAB style string/value pairs or with python kwargs. For example, the following are equivalent:

```python
>>> setp(lines, 'linewidth', 2, 'color', 'r') # MATLAB style
>>> setp(lines, linewidth=2, color='r')    # python style
```

`matplotlib.pyplot.show(*args, **kw)`
Display a figure. When running in ipython with its pylab mode, display all figures and return to the ipython prompt.

In non-interactive mode, display all figures and block until the figures have been closed; in interactive mode it has no effect unless figures were created prior to a change from non-interactive to interactive mode (not recommended). In that case it displays the figures but does not block.

A single experimental keyword argument, `block`, may be set to True or False to override the blocking behavior described above.

`matplotlib.pyplot.specgram(x, NFFT=None, Fs=None, Fc=None, detrend=mlab.detrend_none, window=mlab.window_hanning, noverlap=128, cmap=None, xextent=None, pad_to=None, sides='default', scale_by_freq=None, mode='default', scale='default', **kwargs)`
Plot a spectrogram.

Call signature:

```python
specgram(x, NFFT=256, Fs=2, Fc=0, detrend=mlab.detrend_none, window=mlab.window_hanning, noverlap=128,
    cmap=None, xextent=None, pad_to=None, sides='default', scale_by_freq=None, mode='default', scale='default',
    **kwargs)
```

Compute and plot a spectrogram of data in `x`. Data are split into `NFFT` length segments and the spectrum of each section is computed. The windowing function `window` is applied to each segment, and the amount of overlap of each segment is specified with `noverlap`. The spectrogram is plotted as a colormap (using imshow).

**Parameters**

- `x` : 1-D array or sequence
  Array or sequence containing the data.
- `Fs` : scalar
  The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, freqs, in cycles per time unit. The default value is 2.

---

1524 Chapter 44. pyplot
window : callable or ndarray

A function or a vector of length NFFT. To create window vectors see window_hanning(), window_none(), numpy.blackman(), numpy.hamming(), numpy.bartlett(), scipy.signal(), scipy.signal.get_window(), etc. The default is window_hanning(). If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.

sides : [‘default’ | ‘onesided’ | ‘twosided’ ]

Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.

pad_to : integer

The number of points to which the data segment is padded when performing the FFT. This can be different from NFFT, which specifies the number of data points used. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the n parameter in the call to fft(). The default is None, which sets pad_to equal to NFFT

NFFT : integer

The number of data points used in each block for the FFT. A power 2 is most efficient. The default value is 256. This should NOT be used to get zero padding, or the scaling of the result will be incorrect. Use pad_to for this instead.

detrend : {‘default’, ‘constant’, ‘mean’, ‘linear’, ‘none’} or callable

The function applied to each segment before fft-ing, designed to remove the mean or linear trend. Unlike in MATLAB, where the detrend parameter is a vector, in matplotlib it is a function. The pylab module defines detrend_none(), detrend_mean(), and detrend_linear(), but you can use a custom function as well. You can also use a string to choose one of the functions. ‘default’, ‘constant’, and ‘mean’ call detrend_mean(). ‘linear’ calls detrend_linear(). ‘none’ calls detrend_none().

scale_by_freq : boolean, optional

Specifies whether the resulting density values should be scaled by the scaling frequency, which gives density in units of Hz^-1. This allows for integration over the returned frequency values. The default is True for MATLAB compatibility.

mode : [ ‘default’ | ‘psd’ | ‘magnitude’ | ‘angle’ | ‘phase’ ]

What sort of spectrum to use. Default is ‘psd’, which takes the power spectral density. ‘complex’ returns the complex-valued frequency spectrum. ‘mag-
The magnitude spectrum. ‘angle’ returns the phase spectrum without unwrapping. ‘phase’ returns the phase spectrum with unwrapping.

**nooverlap** : integer

The number of points of overlap between blocks. The default value is 128.

**scale** : [ ‘default’ | ‘linear’ | ‘dB’ ]

The scaling of the values in the spec. ‘linear’ is no scaling. ‘dB’ returns the values in dB scale. When mode is ‘psd’, this is dB power (10 * log10). Otherwise this is dB amplitude (20 * log10). ‘default’ is ‘dB’ if mode is ‘psd’ or ‘magnitude’ and ‘linear’ otherwise. This must be ‘linear’ if mode is ‘angle’ or ‘phase’.

**Fc** : integer

The center frequency of x (defaults to 0), which offsets the x extents of the plot to reflect the frequency range used when a signal is acquired and then filtered and downsampled to baseband.

**cmap** :

A matplotlib.colors.Colormap instance; if None, use default determined by rc

**xextent** : [None | (xmin, xmax)]

The image extent along the x-axis. The default sets xmin to the left border of the first bin (spectrum column) and xmax to the right border of the last bin. Note that for nooverlap>0 the width of the bins is smaller than those of the segments.

****kwargs** :

Additional kwargs are passed on to imshow which makes the specgram image

Returns **spectrum** : 2-D array

Columns are the periodograms of successive segments.

**freqs** : 1-D array

The frequencies corresponding to the rows in spectrum.

**t** : 1-D array

The times corresponding to midpoints of segments (i.e., the columns in spectrum).

**im** : instance of class AxesImage

The image created by imshow containing the spectrogram

See also:

**psd() psd()** differs in the default overlap; in returning the mean of the segment periodograms; in not returning times; and in generating a line plot instead of colormap.
**magnitude_spectrum()** A single spectrum, similar to having a single segment when *mode* is ‘magnitude’. Plots a line instead of a colormap.

**angle_spectrum()** A single spectrum, similar to having a single segment when *mode* is ‘angle’. Plots a line instead of a colormap.

**phase_spectrum()** A single spectrum, similar to having a single segment when *mode* is ‘phase’. Plots a line instead of a colormap.

In addition to the above described arguments, this function can take a **data** keyword argument. If such a **data** argument is given, the following arguments are replaced by **data[<arg>]**: * All arguments with the following names: ‘x’.

**Notes**

*detrend* and *scale_by_freq* only apply when *mode* is set to ‘psd’

**Examples**

```python
matplotlib.pyplot.spectral()
```

set the default colormap to spectral and apply to current image if any. See help(colormaps) for more information.
```python
matplotlib.pyplot.spring()

set the default colormap to spring and apply to current image if any. See help(colormaps) for more information

matplotlib.pyplot.spy(Z, precision=0, marker=None, markersize=None, aspect='equal', **kwargs)

Plot the sparsity pattern on a 2-D array.

spy(Z) plots the sparsity pattern of the 2-D array Z.

Parameters

- **Z** : sparse array (n, m)
  - The array to be plotted.

- **precision** : float, optional, default: 0
  - If precision is 0, any non-zero value will be plotted; else, values of |Z| > precision will be plotted.

  For `scipy.sparse.spmatrix` instances, there is a special case: if precision is ‘present’, any value present in the array will be plotted, even if it is identically zero.

- **origin** : ["upper", “lower”], optional, default: “upper”
  - Place the [0,0] index of the array in the upper left or lower left corner of the axes.

- **aspect** : [‘auto’ | ‘equal’ | scalar], optional, default: “equal”
  - If ‘equal’, and extent is None, changes the axes aspect ratio to match that of the image. If extent is not None, the axes aspect ratio is changed to match that of the extent.

  If ‘auto’, changes the image aspect ratio to match that of the axes.

  If None, default to rc image.aspect value.

Two plotting styles are available: image or marker. Both are available for full arrays, but only the marker style works for `scipy.sparse.spmatrix` instances.

If *marker* and *markersize* are *None*, an image will be returned and any remaining kwargs are passed to :func:`~matplotlib.pyplot.imshow`; else, a :class:`~matplotlib.lines.Line2D` object will be returned with the value of marker determining the marker type, and any remaining kwargs passed to the :meth:`~matplotlib.axes.Axes.plot` method.

If *marker* and *markersize* are *None*, useful kwargs include:
```
**cmap**
**alpha**

See also:

`imshow` for image options.
`plot` for plotting options

```python
matplotlib.pyplot.stackplot(x, *args, **kwargs)
```

Draws a stacked area plot.

- `x`: 1d array of dimension N
- `y`: [2d array of dimension MxN, OR any number 1d arrays each of dimension] 1xN. The data is assumed to be unstacked. Each of the following calls is legal:

```python
stackplot(x, y) # where y is MxN
stackplot(x, y1, y2, y3, y4) # where y1, y2, y3, y4, are all 1xNm
```

Keyword arguments:

- `baseline`: [[‘zero’, ‘sym’, ‘wiggle’, ‘weighted_wiggle’]] Method used to calculate the baseline. ‘zero’ is just a simple stacked plot. ‘sym’ is symmetric around zero and is sometimes called ThemeRiver. ‘wiggle’ minimizes the sum of the squared slopes. ‘weighted_wiggle’ does the same but weights to account for size of each layer. It is also called Streamgraph-layout. More details can be found at http://leebyron.com/streamgraph/.

- `labels`: A list or tuple of labels to assign to each data series.

- `colors`: [A list or tuple of colors. These will be cycled through and] used to colour the stacked areas.
  
  All other keyword arguments are passed to `fill_between`

Returns `r`: A list of `PolyCollection`, one for each element in the stacked area plot.

```python
matplotlib.pyplot.stem(*args, **kwargs)
```

Create a stem plot.

Call signatures:

```python
stem(y, linefmt='b-', markerfmt='bo', basefmt='r-')
stem(x, y, linefmt='b-', markerfmt='bo', basefmt='r-')
```

A stem plot plots vertical lines (using `linefmt`) at each x location from the baseline to y, and places a marker there using `markerfmt`. A horizontal line at 0 is is plotted using `basefmt`.

If no x values are provided, the default is (0, 1, ..., len(y) - 1)

Return value is a tuple (`markerline, stemlines, baseline`).

See also:

This document for details.

Example:
**Note:** In addition to the above described arguments, this function can take a **data** keyword argument. If such a **data** argument is given, the following arguments are replaced by **data[<arg>]**:

- All positional and all keyword arguments.

```python
matplotlib.pyplot.step(x, y, *args, **kwargs)
```

Make a step plot.

**Parameters**

**x** : array_like

1-D sequence, and it is assumed, but not checked, that it is uniformly increasing.

**y** : array_like

1-D sequence, and it is assumed, but not checked, that it is uniformly increasing.

**Returns**

list

List of lines that were added.

**Other Parameters where** : [ ‘pre’ | ‘post’ | ‘mid’ ]

If ‘pre’ (the default), the interval from x[i] to x[i+1] has level y[i+1].
If ‘post’, that interval has level $y[i]$.
If ‘mid’, the jumps in $y$ occur half-way between the $x$-values.

**Notes**

Additional parameters are the same as those for `plot()`.

---

**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]:`

- All arguments with the following names: ‘x’, ‘y’.

```python
matplotlib.pyplot.streamplot(x, y, u, v, density=1, linewidth=None, color=None, cmap=None, norm=None, arrowsize=1, arrowstyle='-', minlength=0.1, transform=None, zorder=None, start_points=None, hold=None, data=None)
```

Draws streamlines of a vector flow.

**x, y** [1d arrays] an *evenly spaced* grid.

**u, v** [2d arrays] $x$ and $y$-velocities. Number of rows should match length of $y$, and the number of columns should match $x$.

**density** [float or 2-tuple] Controls the closeness of streamlines. When density = 1, the domain is divided into a 30x30 grid—density linearly scales this grid. Each cell in the grid can have, at most, one traversing streamline. For different densities in each direction, use [density$_x$, density$_y$].

**linewidth** [numeric or 2d array] vary linewidth when given a 2d array with the same shape as velocities.

**color** [matplotlib color code, or 2d array] Streamline color. When given an array with the same shape as velocities, color values are converted to colors using `cmap`.

**cmap** [Colormap] Colormap used to plot streamlines and arrows. Only necessary when using an array input for `color`.

**norm** [Normalize] Normalize object used to scale luminance data to 0, 1. If None, stretch (min, max) to (0, 1). Only necessary when `color` is an array.

**arrowsize** [float] Factor scale arrow size.

**arrowstyle** [str] Arrow style specification. See *FancyArrowPatch*.

**minlength** [float] Minimum length of streamline in axes coordinates.

**start_points**: **Nx2 array** Coordinates of starting points for the streamlines. In data coordinates, the same as the $x$ and $y$ arrays.

**zorder** [int] any number

Returns:

**44.1. matplotlib.pyplot**
stream_container [StreamplotSet] Container object with attributes

- lines: matplotlib.collections.LineCollection of streamlines
- arrows: collection of matplotlib.patches.FancyArrowPatch objects representing arrows half-way along stream lines.

This container will probably change in the future to allow changes to the colormap, alpha, etc. for both lines and arrows, but these changes should be backward compatible.

matplotlib.pyplot.subplot(*args, **kwargs)

Return a subplot axes positioned by the given grid definition.

Typical call signature:

```python
subplot(nrows, ncols, plot_number)
```

Where `nrows` and `ncols` are used to notionally split the figure into `nrows * ncols` sub-axes, and `plot_number` is used to identify the particular subplot that this function is to create within the notional grid. `plot_number` starts at 1, increments across rows first and has a maximum of `nrows * ncols`.

In the case when `nrows`, `ncols` and `plot_number` are all less than 10, a convenience exists, such that the a 3 digit number can be given instead, where the hundreds represent `nrows`, the tens represent `ncols` and the units represent `plot_number`. For instance:

```python
subplot(211)
```

produces a subaxes in a figure which represents the top plot (i.e. the first) in a 2 row by 1 column notional grid (no grid actually exists, but conceptually this is how the returned subplot has been positioned).

**Note:** Creating a new subplot with a position which is entirely inside a pre-existing axes will trigger the larger axes to be deleted:

```python
import matplotlib.pyplot as plt
# plot a line, implicitly creating a subplot(111)
plt.plot([1,2,3])
# now create a subplot which represents the top plot of a grid
# with 2 rows and 1 column. Since this subplot will overlap the
# first, the plot (and its axes) previously created, will be removed
plt.subplot(211)
plt.plot(range(12))
plt.subplot(212, facecolor='y') # creates 2nd subplot with yellow background
```

If you do not want this behavior, use the `add_subplot()` method or the `axes()` function instead.

Keyword arguments:

- `facecolor`: The background color of the subplot, which can be any valid color specifier. See `matplotlib.colors` for more information.
**polar**: A boolean flag indicating whether the subplot plot should be a polar projection. Defaults to *False*.

**projection**: A string giving the name of a custom projection to be used for the subplot. This projection must have been previously registered. See *matplotlib.projections*.

See also:

*axes()* For additional information on *axes()* and *subplot()* keyword arguments.

*examples/pie_and_polar_charts/polar_scatter_demo.py* For an example

Example:

```python
matplotlib.pyplot.subplot2grid(shape, loc, rowspan=1, colspan=1, **kwargs)
```

Create a subplot in a grid. The grid is specified by *shape*, at location of *loc*, spanning *rowspan*, *colspan* cells in each direction. The index for *loc* is 0-based.

```python
subplot2grid(shape, loc, rowspan=1, colspan=1)
```

is identical to

```python
gridspec=GridSpec(shape[0], shape[1])
subplotspec=gridspec.new_subplotspec(loc, rowspan, colspan)
subplot(subplotspec)
```
matplotlib.pyplot.subplot_tool(targetfig=None)
Launch a subplot tool window for a figure.
A matplotlib.widgets.SubplotTool instance is returned.

matplotlib.pyplot.subplots(nrows=1, ncols=1, sharex=False, sharey=False, squeeze=True,
subplot_kw=None, gridspec_kw=None, **fig_kw)
Create a figure and a set of subplots
This utility wrapper makes it convenient to create common layouts of subplots, including the enclosing figure object, in a single call.

Parameters:

nrows, ncols : int, optional, default: 1
Number of rows/columns of the subplot grid.

sharex, sharey : bool or {'none', 'all', 'row', 'col'}, default: False
Controls sharing of properties among x (sharex) or y (sharey) axes:

- True or 'all': x- or y-axis will be shared among all subplots.
- False or 'none': each subplot x- or y-axis will be independent.
- 'row': each subplot row will share an x- or y-axis.
- 'col': each subplot column will share an x- or y-axis.

When subplots have a shared x-axis along a column, only the x tick labels of the bottom subplot are visible. Similarly, when subplots have a shared y-axis along a row, only the y tick labels of the first column subplot are visible.

squeeze : bool, optional, default: True

- If True, extra dimensions are squeezed out from the returned Axes object:
  - if only one subplot is constructed (nrows=ncols=1), the resulting single Axes object is returned as a scalar.
  - for Nx1 or 1xN subplots, the returned object is a 1D numpy object array of Axes objects are returned as numpy 1D arrays.
  - for NxM, subplots with N>1 and M>1 are returned as a 2D arrays.
- If False, no squeezing at all is done: the returned Axes object is always a 2D array containing Axes instances, even if it ends up being 1x1.

subplot_kw : dict, optional
Dict with keywords passed to the add_subplot() call used to create each subplot.

gridspec_kw : dict, optional
Dict with keywords passed to the GridSpec constructor used to create the grid the subplots are placed on.

fig_kw : dict, optional
Dict with keywords passed to the `figure()` call. Note that all keywords not recognized above will be automatically included here.

**Returns** `fig`: `matplotlib.figure.Figure` object

`ax`: Axes object or array of Axes objects.

`ax` can be either a single `matplotlib.axes.Axes` object or an array of Axes objects if more than one subplot was created. The dimensions of the resulting array can be controlled with the `squeeze` keyword, see above.

**See also:**

`figure`, `subplot`

**Examples**

First create some toy data:

```python
>>> x = np.linspace(0, 2*np.pi, 400)
>>> y = np.sin(x**2)
```

Creates just a figure and only one subplot

```python
>>> fig, ax = plt.subplots()
>>> ax.plot(x, y)
>>> ax.set_title('Simple plot')
```

Creates two subplots and unpacks the output array immediately

```python
>>> f, (ax1, ax2) = plt.subplots(1, 2, sharey=True)
>>> ax1.plot(x, y)
>>> ax1.set_title('Sharing Y axis')
>>> ax2.scatter(x, y)
```

Creates four polar axes, and accesses them through the returned array

```python
>>> fig, axes = plt.subplots(2, 2, subplot_kw=dict(polar=True))
>>> axes[0, 0].plot(x, y)
>>> axes[1, 1].scatter(x, y)
```

Share a X axis with each column of subplots

```python
>>> plt.subplots(2, 2, sharex='col')
```

Share a Y axis with each row of subplots

```python
>>> plt.subplots(2, 2, sharey='row')
```

Share both X and Y axes with all subplots
>>> plt.subplots(2, 2, sharex='all', sharey='all')

Note that this is the same as

>>> plt.subplots(2, 2, sharex=True, sharey=True)

matplotlib.pyplot.subplots_adjust(*args, **kwargs)

Tune the subplot layout.

call signature:

subplots_adjust(left=None, bottom=None, right=None, top=None, 
                wspace=None, hspace=None)

The parameter meanings (and suggested defaults) are:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>left</td>
<td>0.125</td>
<td>the left side of the subplots of the figure</td>
</tr>
<tr>
<td>right</td>
<td>0.9</td>
<td>the right side of the subplots of the figure</td>
</tr>
<tr>
<td>bottom</td>
<td>0.1</td>
<td>the bottom of the subplots of the figure</td>
</tr>
<tr>
<td>top</td>
<td>0.9</td>
<td>the top of the subplots of the figure</td>
</tr>
<tr>
<td>wspace</td>
<td>0.2</td>
<td>the amount of width reserved for blank space between subplots,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>expressed as a fraction of the average axis width</td>
</tr>
<tr>
<td>hspace</td>
<td>0.2</td>
<td>the amount of height reserved for white space between subplots,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>expressed as a fraction of the average axis height</td>
</tr>
</tbody>
</table>

The actual defaults are controlled by the rc file

matplotlib.pyplot.summer()

set the default colormap to summer and apply to current image if any. See help(colormaps) for more information

matplotlib.pyplot.suptitle(*args, **kwargs)

Add a centered title to the figure.

kwars are matplotlib.text.Text properties. Using figure coordinates, the defaults are:

- x [0.5] The x location of the text in figure coords
- y [0.98] The y location of the text in figure coords

horizontalalignment ['center'] The horizontal alignment of the text

verticalalignment ['top'] The vertical alignment of the text

If the fontproperties keyword argument is given then the rcParams defaults for fontsize (figure.titlesize) and fontweight (figure.titleweight) will be ignored in favour of the FontProperties defaults.

A matplotlib.text.Text instance is returned.

Example:

fig.suptitle('this is the figure title', fontsize=12)
**matplotlib.pyplot.switch_backend** *(newbackend)*

Switch the default backend. This feature is *experimental*, and is only expected to work switching to an image backend. e.g., if you have a bunch of PostScript scripts that you want to run from an interactive ipython session, you may want to switch to the PS backend before running them to avoid having a bunch of GUI windows popup. If you try to interactively switch from one GUI backend to another, you will explode.

Calling this command will close all open windows.

**matplotlib.pyplot.table** (**kwargs**)

Add a table to the current axes.

Call signature:

```python
table(cellText=None, cellColours=None, cellLoc='right', colWidths=None, rowLabels=None, rowColours=None, rowLoc='left', colLabels=None, colColours=None, colLoc='center', loc='bottom', bbox=None):
```

Returns a `matplotlib.table.Table` instance. Either `cellText` or `cellColours` must be provided. For finer grained control over tables, use the `Table` class and add it to the axes with `add_table()`.

Thanks to John Gill for providing the class and table.

**kwargs control the Table properties:**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>agg_filter</code></td>
<td>unknown</td>
</tr>
<tr>
<td><code>alpha</code></td>
<td>float (0.0 transparent through 1.0 opaque)</td>
</tr>
<tr>
<td><code>animated</code></td>
<td>[True</td>
</tr>
<tr>
<td><code>axes</code></td>
<td>an <code>Axes</code> instance</td>
</tr>
<tr>
<td><code>clip_box</code></td>
<td>a <code>matplotlib.transforms.Bbox</code> instance</td>
</tr>
<tr>
<td><code>clip_on</code></td>
<td>[True</td>
</tr>
<tr>
<td><code>clip_path</code></td>
<td>[(<code>Path</code>, <code>Transform</code>)</td>

<td>unknown</td>
</tr>
<tr>
<td><code>transform</code></td>
<td><code>Transform</code> instance</td>
</tr>
<tr>
<td><code>url</code></td>
<td>a url string</td>
</tr>
<tr>
<td><code>visible</code></td>
<td>[True</td>
</tr>
<tr>
<td><code>zorder</code></td>
<td>any number</td>
</tr>
</tbody>
</table>
matplotlib.pyplot.text(x, y, s, fontdict=None, withdash=False, **kwargs)
Add text to the axes.

Add text in string s to axis at location x, y, data coordinates.

**Parameters**

- **x, y**: scalars
data coordinates
- **s**: string
text
- **fontdict**: dictionary, optional, default: None
  A dictionary to override the default text properties. If fontdict is None, the
defaults are determined by your rc parameters.
- **withdash**: boolean, optional, default: False
  Creates a TextWithDash instance instead of a Text instance.

**Other Parameters**

- **kwargs**: Text properties.
  Other miscellaneous text parameters.

**Examples**

Individual keyword arguments can be used to override any given parameter:

```python
>>> text(x, y, s, fontsize=12)
```

The default transform specifies that text is in data coords, alternatively, you can specify text in axis
cords (0,0 is lower-left and 1,1 is upper-right). The example below places text in the center of the
axes:

```python
>>> text(0.5, 0.5, 'matplotlib', horizontalalignment='center',
       ...       verticalalignment='center',
       ...       transform=ax.transAxes)
```

You can put a rectangular box around the text instance (e.g., to set a background color) by using the
keyword bbox. bbox is a dictionary of Rectangle properties. For example:

```python
>>> text(x, y, s, bbox=dict(facecolor='red', alpha=0.5))
```

**matplotlib.pyplot.thetagrids(**args, **kwargs)**
Get or set the theta locations of the gridlines in a polar plot.

If no arguments are passed, return a tuple `(lines, labels)` where `lines` is an array of radial gridlines
(`Line2D` instances) and `labels` is an array of tick labels (`Text` instances):

```python
lines, labels = thetagrids()
```

Otherwise the syntax is:
set the angles at which to place the theta grids (these gridlines are equal along the theta dimension).

angles is in degrees.

labels, if not None, is a len(angles) list of strings of the labels to use at each angle.

If labels is None, the labels will be fmt%angle.

frac is the fraction of the polar axes radius at which to place the label (1 is the edge). e.g., 1.05 is outside the axes and 0.95 is inside the axes.

Return value is a list of tuples (lines, labels):

- lines are Line2D instances
- labels are Text instances.

Note that on input, the labels argument is a list of strings, and on output it is a list of Text instances.

Examples:

```python
# set the locations of the radial gridlines and labels
lines, labels = thetagrids( range(45,360,90) )

# set the locations and labels of the radial gridlines and labels
lines, labels = thetagrids( range(45,360,90), ('NE', 'NW', 'SW', 'SE') )
```

matplotlib.pyplot.tick_params(axis='both', **kwargs)

Change the appearance of ticks and tick labels.

**Parameters**

- **axis**: {'x', 'y', 'both'}, optional
  
  Which axis to apply the parameters to.

- **Other Parameters**

  - **axis**: {'x', 'y', 'both'}
    
    Axis on which to operate; default is ‘both’.

  - **reset**: bool
    
    If True, set all parameters to defaults before processing other keyword arguments. Default is False.

  - **which**: {'major', 'minor', 'both'}
    
    Default is ‘major’; apply arguments to which ticks.

  - **direction**: {'in', 'out', 'inout'}
    
    Puts ticks inside the axes, outside the axes, or both.

  - **length**: float
    
    Tick length in points.

  - **width**: float
Tick width in points.

**color** : color

Tick color; accepts any mpl color spec.

**pad** : float

Distance in points between tick and label.

**labelsize** : float or str

Tick label font size in points or as a string (e.g., ‘large’).

**labelcolor** : color

Tick label color; mpl color spec.

**colors** : color

Changes the tick color and the label color to the same value: mpl color spec.

**zorder** : float

Tick and label zorder.

**bottom, top, left, right** : bool or {'on', 'off'}

controls whether to draw the respective ticks.

**labelbottom, labeltop, labelleft, labelright** : bool or {'on', 'off'}

controls whether to draw the respective tick labels.

**Examples**

Usage

```python
ax.tick_params(direction='out', length=6, width=2, colors='r')
```

This will make all major ticks be red, pointing out of the box, and with dimensions 6 points by 2 points. Tick labels will also be red.

```
matplotlib.pyplot.ticklabel_format(**kwargs)
```

Change the *ScalarFormatter* used by default for linear axes.

Optional keyword arguments:
<table>
<thead>
<tr>
<th><strong>Keyword</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>style</strong></td>
<td>['sci' (or 'scientific')</td>
</tr>
<tr>
<td><strong>scilimits</strong></td>
<td>(m, n), pair of integers; if <strong>style</strong> is ‘sci’, scientific notation will be used for numbers outside the range $10^m$ to $10^n$. Use (0,0) to include all numbers.</td>
</tr>
<tr>
<td><strong>useOffset</strong></td>
<td>[True</td>
</tr>
<tr>
<td><strong>axis</strong></td>
<td>['x'</td>
</tr>
<tr>
<td><strong>useLocale</strong></td>
<td>If True, format the number according to the current locale. This affects things such as the character used for the decimal separator. If False, use C-style (English) formatting. The default setting is controlled by the axes.formatter.use_locale rcparam.</td>
</tr>
</tbody>
</table>

Only the major ticks are affected. If the method is called when the ScalarFormatter is not the Formatter being used, an AttributeError will be raised.

```python
matplotlib.pyplot.tight_layout(pad=1.08, h_pad=None, w_pad=None, rect=None)
```

Automatically adjust subplot parameters to give specified padding.

**Parameters:**

- **pad** [float] padding between the figure edge and the edges of subplots, as a fraction of the font-size.
- **h_pad**, **w_pad** [float] padding (height/width) between edges of adjacent subplots. Defaults to `pad_inches`.
- **rect** [if rect is given, it is interpreted as a rectangle] (left, bottom, right, top) in the normalized figure coordinate that the whole subplots area (including labels) will fit into. Default is (0, 0, 1, 1).

```python
matplotlib.pyplot.title(s, *args, **kwargs)
```

Set a title of the current axes.

Set one of the three available axes titles. The available titles are positioned above the axes in the center, flush with the left edge, and flush with the right edge.

**See also:**

See `text()` for adding text to the current axes

**Parameters**

- **label** : str
  
  Text to use for the title

- **fontdict** : dict

  A dictionary controlling the appearance of the title text, the default `fontdict` is:

  ```
  {'fontsize': rcParams['axes.titlesize'], 'fontweight': rcParams['axes.titleweight'], 'verticalalignment': 'baseline', 'horizontalalignment': 'center'}
  ```

  - **loc** : {'center', 'left', 'right'}, str, optional
Which title to set, defaults to ‘center’

**Returns text**: `Text`

The matplotlib text instance representing the title

**Other Parameters kwargs**: text properties

Other keyword arguments are text properties, see `Text` for a list of valid text properties.

```
matplotlib.pyplot.tricontour(*args, **kwargs)
```

Draw contours on an unstructured triangular grid. `tricontour()` and `tricontourf()` draw contour lines and filled contours, respectively. Except as noted, function signatures and return values are the same for both versions.

The triangulation can be specified in one of two ways; either:

```
tricontour(triangulation, ...)
```

where triangulation is a `matplotlib.tri.Triangulation` object, or

```
tricontour(x, y, ...)
tricontour(x, y, triangles, ...)
tricontour(x, y, triangles=triangles, ...)
tricontour(x, y, mask=mask, ...)
tricontour(x, y, triangles, mask=mask, ...)
```

in which case a Triangulation object will be created. See `Triangulation` for an explanation of these possibilities.

The remaining arguments may be:

```
tricontour(..., Z)
```

where Z is the array of values to contour, one per point in the triangulation. The level values are chosen automatically.

```
tricontour(..., Z, N)
```

contour N automatically-chosen levels.

```
tricontour(..., Z, V)
```

draw contour lines at the values specified in sequence V, which must be in increasing order.

```
tricontourf(..., Z, V)
```

fill the (len(V)-1) regions between the values in V, which must be in increasing order.

```
tricontour(Z, **kwargs)
```

Use keyword args to control colors, linewidth, origin, cmap ... see below for more details.
C = tricontour(...) returns a TriContourSet object.

Optional keyword arguments:

**colors**: [ *None* | *string* | *(mpl_colors)* ] If *None*, the colormap specified by *cmap* will be used.

- If a string, like ‘r’ or ‘red’, all levels will be plotted in this color.
- If a tuple of matplotlib color args (string, float, rgb, etc), different levels will be plotted in different colors in the order specified.

**alpha**: float The alpha blending value

**cmap**: [ *None* | *Colormap* ] A cm *Colormap* instance or *None*. If *cmap* is *None* and *colors* is *None*, a default Colormap is used.

**norm**: [ *None* | *Normalize* ] A *matplotlib.colors.Normalize* instance for scaling data values to colors. If *norm* is *None* and *colors* is *None*, the default linear scaling is used.

**levels** [level0, level1, ..., leveln] A list of floating point numbers indicating the level curves to draw, in increasing order; e.g., to draw just the zero contour pass *levels=[0]*

**origin**: [ *None* | ‘upper’ | ‘lower’ | ‘image’ ] If *None*, the first value of *Z* will correspond to the lower left corner, location (0,0). If ‘image’, the rc value for *image.origin* will be used.

This keyword is not active if *X* and *Y* are specified in the call to *contour*.

**extent**: [ *None* | (*x0*,*x1*,*y0*,*y1*) ]

- If *origin* is not *None*, then *extent* is interpreted as in *matplotlib.pyplot.imshow()*: it gives the outer pixel boundaries. In this case, the position of *Z*[0,0] is the center of the pixel, not a corner. If *origin* is *None*, then (*x0*, *y0*) is the position of *Z*[0,0], and (*x1*, *y1*) is the position of *Z*[-1,-1].

This keyword is not active if *X* and *Y* are specified in the call to *contour*.

**locator**: [ *None* | *ticker.Locator subclass* ] If *locator* is *None*, the default *MaxNLocator* is used. The locator is used to determine the contour levels if they are not given explicitly via the *V* argument.

**extend**: [ ‘neither’ | ‘both’ | ‘min’ | ‘max’ ] Unless this is ‘neither’, contour levels are automatically added to one or both ends of the range so that all data are included. These added ranges are then mapped to the special colormap values which default to the ends of the colormap range, but can be set via *matplotlib.colors.Colormap.set_under()* and *matplotlib.colors.Colormap.set_over()* methods.

**xunits, yunits**: [ *None* | *registered units* ] Override axis units by specifying an instance of a *matplotlib.units.ConversionInterface*.

tricontour-only keyword arguments:

**linewidths**: [ *None* | *number* | *tuple of numbers* ] If *linewidths* is *None*, the default width in *lines.linewidth* in *matplotlibrc* is used.
If a number, all levels will be plotted with this linewidth.

If a tuple, different levels will be plotted with different linewidths in the order specified

\textit{linestyles}: \[ \text{None} \mid \text{solid} \mid \text{dashed} \mid \text{dashdot} \mid \text{dotted} \]

If \textit{linestyles} is \text{None}, the ‘solid’ is used.

\textit{linestyles} can also be an iterable of the above strings specifying a set of linestyles to be used. If this iterable is shorter than the number of contour levels it will be repeated as necessary.

If contour is using a monochrome colormap and the contour level is less than 0, then the linestyle specified in \textit{contour.negative_linestyle} in \texttt{matplotlibrc} will be used.

tricontourf-only keyword arguments:

\textit{antialiased}: \[ \text{True} \mid \text{False} \]
enable antialiasing

Note: tricontourf fills intervals that are closed at the top; that is, for boundaries $z_1$ and $z_2$, the filled region is:

\begin{equation}
\begin{array}{c}
z_1 < z \leq z_2 \\
\end{array}
\end{equation}

There is one exception: if the lowest boundary coincides with the minimum value of the $z$ array, then that minimum value will be included in the lowest interval.

\textbf{Examples}:
Contour plot of Delaunay triangulation
matplotlib.pyplot.tricontourf(*args, **kwargs)

Draw contours on an unstructured triangular grid. tricontour() and tricontourf() draw contour lines and filled contours, respectively. Except as noted, function signatures and return values are the same for both versions.

The triangulation can be specified in one of two ways; either:

tricontour(triangulation, ...)

where triangulation is a matplotlib.tri.Triangulation object, or

tricontour(x, y, ...)  
tricontour(x, y, triangles, ...)  
tricontour(x, y, triangles=triangles, ...)  
tricontour(x, y, mask=mask, ...)  
tricontour(x, y, triangles, mask=mask, ...)

in which case a Triangulation object will be created. See Triangulation for a explanation of these possibilities.

The remaining arguments may be:

tricontour(..., Z)

where Z is the array of values to contour, one per point in the triangulation. The level values are chosen automatically.
Matplotlib, Release 2.0.0

```python
tricontour(..., Z, N)
```

contour $N$ automatically-chosen levels.

```python
tricontour(..., Z, V)
```

draw contour lines at the values specified in sequence $V$, which must be in increasing order.

```python
tricontourf(..., Z, V)
```

fill the $(\text{len}(V)-1)$ regions between the values in $V$, which must be in increasing order.

```python
tricontour(Z, **kwargs)
```

Use keyword args to control colors, linewidth, origin, cmap ... see below for more details.

$C = \text{tricontour}(\ldots)$ returns a `TriContourSet` object.

Optional keyword arguments:

- **colors**: [ `None` | string | (mpl_colors) ] If `None`, the colormap specified by cmap will be used.
  - If a string, like ‘r’ or ‘red’, all levels will be plotted in this color.
  - If a tuple of matplotlib color args (string, float, rgb, etc), different levels will be plotted in different colors in the order specified.

- **alpha**: float The alpha blending value

- **cmap**: [ `None` | Colormap ] A `cm Colormap` instance or `None`. If `cmap` is `None` and `colors` is `None`, a default Colormap is used.

- **norm** [ `None` | Normalize ] A `matplotlib.colors.Normalize` instance for scaling data values to colors. If `norm` is `None` and `colors` is `None`, the default linear scaling is used.

- **levels** [level0, level1, ..., leveln] A list of floating point numbers indicating the level curves to draw, in increasing order; e.g., to draw just the zero contour pass `levels=[0]`

- **origin**: [ `None` | ‘upper’ | ‘lower’ | ‘image’ ] If `None`, the first value of $Z$ will correspond to the lower left corner, location $(0,0)$. If ‘image’, the rc value for `image.origin` will be used.
  - This keyword is not active if $X$ and $Y$ are specified in the call to contour.

- **extent**: [ `None` | (x0,x1,y0,y1) ]
  - If `origin` is not `None`, then `extent` is interpreted as in `matplotlib.pyplot.imshow()`: it gives the outer pixel boundaries. In this case, the position of $Z[0,0]$ is the center of the pixel, not a corner. If `origin` is `None`, then $(x0, y0)$ is the position of $Z[0,0]$, and $(x1, y1)$ is the position of $Z[-1,-1]$.
  - This keyword is not active if $X$ and $Y$ are specified in the call to contour.
**locator**: [None | ticker.Locator subclass] If `locator` is None, the default `MaxNLocator` is used. The locator is used to determine the contour levels if they are not given explicitly via the `V` argument.

**extend**: [‘neither’ | ‘both’ | ‘min’ | ‘max’] Unless this is ‘neither’, contour levels are automatically added to one or both ends of the range so that all data are included. These added ranges are then mapped to the special colormap values which default to the ends of the colormap range, but can be set via `matplotlib.colors.Colormap.set_under()` and `matplotlib.colors.Colormap.set_over()` methods.

**xunits, yunits**: [None | registered units] Override axis units by specifying an instance of a `matplotlib.units.ConversionInterface`.

tricontour-only keyword arguments:

**linewidths**: [None | number | tuple of numbers] If `linewidths` is None, the default width in `lines.linewidth` in `matplotlibrc` is used.

If a number, all levels will be plotted with this linewidth.

If a tuple, different levels will be plotted with different linewidths in the order specified.

**linestyles**: [None | ‘solid’ | ‘dashed’ | ‘dashdot’ | ‘dotted’] If `linestyles` is None, the ‘solid’ is used.

`linestyles` can also be an iterable of the above strings specifying a set of linestyles to be used. If this iterable is shorter than the number of contour levels it will be repeated as necessary.

If contour is using a monochrome colormap and the contour level is less than 0, then the linestyle specified in `contour.negative_linestyle` in `matplotlibrc` will be used.

tricontourf-only keyword arguments:

**antialiased**: [True | False] enable antialiasing

Note: tricontourf fills intervals that are closed at the top; that is, for boundaries `z1` and `z2`, the filled region is:

```
z1 < z <= z2
```

There is one exception: if the lowest boundary coincides with the minimum value of the `z` array, then that minimum value will be included in the lowest interval.

**Examples**: 

Contour plot of Delaunay triangulation

```python
import matplotlib.pyplot as plt

delaunay_plot = plt.triplot(X, Y, 'bo-')
plt.tricontourf(X, Y, Z, 15, cmap='autumn')
plt.triplot(X, Y, 'k-')
plt.clim(-1.0, 1.0)
plt.colorbar()
plt.title('Contour plot of Delaunay triangulation')
plt.show()
```
Matplotlib.pyplot.tripcolor(*args, **kwargs)

Create a pseudocolor plot of an unstructured triangular grid.

The triangulation can be specified in one of two ways; either:

```python
tripcolor(triangulation, ...)
```

where triangulation is a :class:`matplotlib.tri.Triangulation` object, or

```python
tripcolor(x, y, ...)
tripcolor(x, y, triangles, ...)
tripcolor(x, y, triangles=triangles, ...)
tripcolor(x, y, mask=mask, ...)
tripcolor(x, y, triangles, mask=mask, ...)
```

in which case a Triangulation object will be created. See :class:`Triangulation` for a explanation of these possibilities.

The next argument must be :math:`C`, the array of color values, either one per point in the triangulation if color values are defined at points, or one per triangle in the triangulation if color values are defined at triangles. If there are the same number of points and triangles in the triangulation it is assumed that color values are defined at points; to force the use of color values at triangles use the kwarg `facecolors*=`C instead of just *C.

`shading` may be ‘flat’ (the default) or ‘gouraud’. If `shading` is ‘flat’ and :math:`C` values are defined at points, the color values used for each triangle are from the mean :math:`C` of the triangle’s three points. If `shading`
is ‘gouraud’ then color values must be defined at points.

The remaining kwargs are the same as for `pcolor()`.

**Example:**

![Tripcolor of Delaunay triangulation, flat shading](image)
tripcolor of Delaunay triangulation, gouraud shading
The triangulation to plot can be specified in one of two ways; either:

```
triplot(triangulation, ...)
```

where triangulation is a `matplotlib.tri.Triangulation` object, or

```
triplot(x, y, ...)
triplot(x, y, triangles, ...)
triplot(x, y, triangles=triangles, ...)
triplot(x, y, mask=mask, ...)
triplot(x, y, triangles, mask=mask, ...)
```

in which case a Triangulation object will be created. See `Triangulation` for a explanation of these possibilities.

The remaining args and kwags are the same as for `plot()`.

Return a list of 2 `Line2D` containing respectively:

- the lines plotted for triangles edges
- the markers plotted for triangles nodes

**Example:**
triplot of Delaunay triangulation
Matplotlib, Release 2.0.0

```
import matplotlib.pyplot as plt

ax = plt.axes()  # Create the main axes

# Plot the triangulation
triplot(ax, x, y, triangles, color='k')

# Add a colorbar
cbar = ax.colorbar()
```

**Step 2: Customize the Plot**

You can customize the plot further by changing the color, line style, or adding additional elements like titles, labels, and annotations.

```
# Change the color of the triangles
triplot(ax, x, y, triangles, color='r')

# Add labels
ax.set_xlabel('Longitude (degrees)')
ax.set_ylabel('Latitude (degrees)')
```
The input data.

**positions**: array-like, default = [1, 2, ..., n]

Sets the positions of the violins. The ticks and limits are automatically set to match the positions.

**vert**: bool, default = True.

If true, creates a vertical violin plot. Otherwise, creates a horizontal violin plot.

**widths**: array-like, default = 0.5

Either a scalar or a vector that sets the maximal width of each violin. The default is 0.5, which uses about half of the available horizontal space.

**showmeans**: bool, default = False

If True, will toggle rendering of the means.

**showextrema**: bool, default = True

If True, will toggle rendering of the extrema.

**showmedians**: bool, default = False

If True, will toggle rendering of the medians.

**points**: scalar, default = 100

Defines the number of points to evaluate each of the gaussian kernel density estimations at.

**bw_method**: str, scalar or callable, optional

The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If a scalar, this will be used directly as `kde.factor`. If a callable, it should take a GaussianKDE instance as its only parameter and return a scalar. If None (default), ‘scott’ is used.

**Returns result**: dict

A dictionary mapping each component of the violinplot to a list of the corresponding collection instances created. The dictionary has the following keys:

- **bodies**: A list of the `matplotlib.collections.PolyCollection` instances containing the filled area of each violin.
- **cmeans**: A `matplotlib.collections.LineCollection` instance created to identify the mean values of each of the violin’s distribution.
- **cmins**: A `matplotlib.collections.LineCollection` instance created to identify the bottom of each violin’s distribution.
- **cmaxes**: A `matplotlib.collections.LineCollection` instance created to identify the top of each violin’s distribution.
• **cbars**: A *matplotlib.collections.LineCollection* instance created to identify the centers of each violin’s distribution.

• **cmedians**: A *matplotlib.collections.LineCollection* instance created to identify the median values of each of the violin’s distribution.

**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

• All arguments with the following names: ‘dataset’.

**matplotlib.pyplot.viridis()**

set the default colormap to viridis and apply to current image if any. See help(colormaps) for more information

**matplotlib.pyplot.vlines(x, ymin, ymax, colors='k', linestyles='solid', label='', hold=None, data=None, **kwargs)**

Plot vertical lines.

Plot vertical lines at each `x` from `ymin` to `ymax`.

**Parameters**

- `x` : scalar or 1D array_like
  x-indexes where to plot the lines.

- `ymin, ymax` : scalar or 1D array_like
  Respective beginning and end of each line. If scalars are provided, all lines will have same length.

- `colors` : array_like of colors, optional, default: ‘k’

- `linestyles` : [‘solid’ | ‘dashed’ | ‘dashdot’ | ‘dotted’], optional

- `label` : string, optional, default: ‘’

**Returns**

- `lines` : *LineCollection*

**Other Parameters**

- `kwargs` : *LineCollection* properties.

See also:

- **hlines** horizontal lines
Examples

![Vertical lines demo](image1)

![Horizontal lines demo](image2)

**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

- All arguments with the following names: ‘colors’, ‘x’, ‘ymax’, ‘ymin’.

```python
matplotlib.pyplot.waitforbuttonpress(*args, **kwargs)
```

Blocking call to interact with the figure.

This will return True is a key was pressed, False if a mouse button was pressed and None if `timeout` was reached without either being pressed.

If `timeout` is negative, does not timeout.

```python
matplotlib.pyplot.winter()
```

set the default colormap to winter and apply to current image if any. See help(colormaps) for more information

```python
matplotlib.pyplot.xcorr(x, y, normed=True, detrend=<function detrend_none>, usevlines=True, maxlags=10, hold=None, data=None, **kwargs)
```

Plot the cross correlation between `x` and `y`.

The correlation with lag k is defined as `sum_n x[n+k] * conj(y[n])`.

**Parameters**

- `x` : sequence of scalars of length n
- `y` : sequence of scalars of length n
- `hold` : boolean, optional, deprecated, default: True
- `detrend` : callable, optional, default: `mlab.detrend_none`
  
  `x` is detrended by the `detrend` callable. Default is no normalization.
normed : boolean, optional, default: True
    if True, input vectors are normalised to unit length.

usevlines : boolean, optional, default: True
    if True, Axes.vlines is used to plot the vertical lines from the origin to the
    acorr. Otherwise, Axes.plot is used.

maxlags : integer, optional, default: 10
    number of lags to show. If None, will return all 2 * len(x) - 1 lags.

Returns (lags, c, line, b) : where:
   • lags are a length 2*maxlags+1 lag vector.
   • c is the 2*maxlags+1 auto correlation vector
   • line is a Line2D instance returned by plot.
   • b is the x-axis (none, if plot is used).

Other Parameters linestyle : Line2D prop, optional, default: None
    Only used if usevlines is False.

marker : string, optional, default: ‘o’

Notes

The cross correlation is performed with numpy.correlate() with mode = 2.

Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[arg]:
   • All arguments with the following names: ‘x’, ‘y’.

matplotlib.pyplot.xkcd(scale=1, length=100, randomness=2)
    Turns on xkcd sketch-style drawing mode. This will only have effect on things drawn after this
    function is called.

For best results, the “Humor Sans” font should be installed: it is not included with matplotlib.

Parameters scale : float, optional
    The amplitude of the wiggle perpendicular to the source line.

length : float, optional
    The length of the wiggle along the line.

randomness : float, optional
    The scale factor by which the length is shrunken or expanded.
Notes

This function works by a number of rcParams, so it will probably override others you have set before. If you want the effects of this function to be temporary, it can be used as a context manager, for example:

```python
with plt.xkcd():
    # This figure will be in XKCD-style
    fig1 = plt.figure()
    # ...

# This figure will be in regular style
fig2 = plt.figure()
```

```
matplotlib.pyplot.xlabel(s, *args, **kwargs)
```

Set the x axis label of the current axis.

Default override is:

```python
override = {
    'fontsize' : 'small',
    'verticalalignment' : 'top',
    'horizontalalignment' : 'center'
}
```

See also:

```
text() For information on how override and the optional args work
```

```
matplotlib.pyplot.xlim(*args, **kwargs)
```

Get or set the x limits of the current axes.

```python
xmin, xmax = xlim() # return the current xlim
xlim( (xmin, xmax) ) # set the xlim to xmin, xmax
xlim( xmin, xmax ) # set the xlim to xmin, xmax
```

If you do not specify args, you can pass the xmin and xmax as kwargs, e.g.:

```python
xlim(xmax=3) # adjust the max leaving min unchanged
xlim(xmin=1) # adjust the min leaving max unchanged
```

Setting limits turns autoscaling off for the x-axis.

The new axis limits are returned as a length 2 tuple.

```
matplotlib.pyplot.xscale(*args, **kwargs)
```

Set the scaling of the x-axis.

call signature:

```python
xscale(scale, **kwargs)
```
The available scales are: ‘linear’ | ‘log’ | ‘logit’ | ‘symlog’

Different keywords may be accepted, depending on the scale:

‘linear’

‘log’

basex/basey: The base of the logarithm

nonposx/nonposy: ['mask' | 'clip'] non-positive values in x or y can be masked as invalid, or clipped to a very small positive number

subsx/subsy: Where to place the subticks between each major tick. Should be a sequence of integers. For example, in a log10 scale: [2, 3, 4, 5, 6, 7, 8, 9]

will place 8 logarithmically spaced minor ticks between each major tick.

‘logit’

nonpos: ['mask' | 'clip'] values beyond ]0, 1[ can be masked as invalid, or clipped to a number very close to 0 or 1

‘symlog’

basex/basey: The base of the logarithm

linthreshx/linthreshy: The range (-x, x) within which the plot is linear (to avoid having the plot go to infinity around zero).

subsx/subsy: Where to place the subticks between each major tick. Should be a sequence of integers. For example, in a log10 scale: [2, 3, 4, 5, 6, 7, 8, 9]

will place 8 logarithmically spaced minor ticks between each major tick.

linscalex/linscaley: This allows the linear range (-linthresh to linthresh) to be stretched relative to the logarithmic range. Its value is the number of decades to use for each half of the linear range. For example, when linscale == 1.0 (the default), the space used for the positive and negative halves of the linear range will be equal to one decade in the logarithmic range.

```
matplotlib.pyplot.xticks(*args, **kwargs)
```

Get or set the x-limits of the current tick locations and labels.

```
# return locs, labels where locs is an array of tick locations and
# labels is an array of tick labels.
locs, labels = xticks()

# set the locations of the xticks
xticks( arange(6) )

# set the locations and labels of the xticks
xticks( arange(5), ('Tom', 'Dick', 'Harry', 'Sally', 'Sue') )
```

The keyword args, if any, are Text properties. For example, to rotate long labels:
```python
taxicks( arange(12), calendar.month_name[1:13], rotation=17 )
```

```python
matplotlib.pyplot.ylabel(s, *args, **kwargs)
Set the y axis label of the current axis.
```

Defaults override is:

```python
override = {
    'fontsize': 'small',
    'verticalalignment': 'center',
    'horizontalalignment': 'right',
    'rotation':'vertical':
}
```

See also:

```python
text() For information on how override and the optional args work.
```

```python
matplotlib.pyplot.ylim(*args, **kwargs)
Get or set the y-limits of the current axes.
```

```python
ymin, ymax = ylim()    # return the current ylim
ylim( (ymin, ymax) )  # set the ylim to ymin, ymax
ylim( ymin, ymax )    # set the ylim to ymin, ymax
```

If you do not specify args, you can pass the `ymin` and `ymax` as kwargs, e.g.:

```python
ylim(ymin=1) # adjust the min leaving max unchanged
ylim(ymax=3) # adjust the max leaving min unchanged
```

Setting limits turns autoscaling off for the y-axis.

The new axis limits are returned as a length 2 tuple.

```python
matplotlib.pyplot.yscale(*args, **kwargs)
Set the scaling of the y-axis.
```

call signature:

```python
yscale(scale, **kwargs)
```

The available scales are: 'linear' | 'log' | 'logit' | 'symlog'

Different keywords may be accepted, depending on the scale:

'linear'

'log'

- `baseX/baseY`: The base of the logarithm
- `nonposx/nonposy`: ['mask' | 'clip'] non-positive values in x or y can be masked as invalid, or clipped to a very small positive number
subsx/subsy: Where to place the subticks between each major tick. Should be a sequence of integers. For example, in a log10 scale: \([2, 3, 4, 5, 6, 7, 8, 9]\)

will place 8 logarithmically spaced minor ticks between each major tick.

‘logit’

nonpos: ['mask' | ‘clip’ ] values beyond \([0, 1]\) can be masked as invalid, or clipped to a number very close to 0 or 1

‘symlog’

basex/basey: The base of the logarithm

linthreshx/linthreshy: The range \((-x, x)\) within which the plot is linear (to avoid having the plot go to infinity around zero).

subsx/subsy: Where to place the subticks between each major tick. Should be a sequence of integers. For example, in a log10 scale: \([2, 3, 4, 5, 6, 7, 8, 9]\)

will place 8 logarithmically spaced minor ticks between each major tick.

linscalex/linscaley: This allows the linear range \((-\text{linthresh} \text{ to } \text{linthresh})\) to be stretched relative to the logarithmic range. Its value is the number of decades to use for each half of the linear range. For example, when \(\text{linscale} == 1.0\) (the default), the space used for the positive and negative halves of the linear range will be equal to one decade in the logarithmic range.

matplotlib.pyplot.yticks(*args, **kwargs)

Get or set the y-limits of the current tick locations and labels.

```python
# return locs, labels where locs is an array of tick locations and
# labels is an array of tick labels.
loc, labels = yticks()

# set the locations of the yticks
yticks( arange(6) )

# set the locations and labels of the yticks
yticks( arange(5), ('Tom', 'Dick', 'Harry', 'Sally', 'Sue') )
```

The keyword args, if any, are Text properties. For example, to rotate long labels:

```python
yticks( arange(12), calendar.month_name[1:13], rotation=45 )
```
45.1 matplotlib.rcsetup

The rcsetup module contains the default values and the validation code for customization using matplotlib’s rc settings.

Each rc setting is assigned a default value and a function used to validate any attempted changes to that setting. The default values and validation functions are defined in the rcsetup module, and are used to construct the rcParams global object which stores the settings and is referenced throughout matplotlib.

These default values should be consistent with the default matplotlibrc file that actually reflects the values given here. Any additions or deletions to the parameter set listed here should also be visited to the matplotlibrc.template in matplotlib’s root source directory.

```python
class matplotlib.rcsetup.ValidateInStrings(key, valid, ignorecase=False)
    Bases: object
    valid is a list of legal strings

class matplotlib.rcsetup.ValidateInterval(vmin, vmax, closedmin=True, closedmax=True)
    Bases: object
    Value must be in interval

matplotlib.rcsetup.cycler(*args, **kwargs)
    Creates a cycler.Cycler object much like cycler.cycler(), but includes input validation.
    cycler(arg) cycler(label, itr) cycler(label1=itr1[, label2=itr2[, ...]])
    Form 1 simply copies a given Cycler object.
    Form 2 creates a Cycler from a label and an iterable.
    Form 3 composes a Cycler as an inner product of the pairs of keyword arguments. In other words, all of the iterables are cycled simultaneously, as if through zip().
    Parameters arg : Cycler
        Copy constructor for Cycler.
    label : name
```
The property key. Must be a valid Artist property. For example, ‘color’ or ‘linestyle’. Aliases are allowed, such as ‘c’ for ‘color’ and ‘lw’ for ‘linewidth’.

itr : iterable
Finite-length iterable of the property values. These values are validated and will raise a ValueError if invalid.

Returns
cycler : Cycler
New cycler.Cycler for the given properties

matplotlib.rcsetup.deprecate_axes_colorcycle(value)

matplotlib.rcsetup.deprecate_axes_hold(value)

matplotlib.rcsetup.deprecate_savefig_extension(value)

matplotlib.rcsetup.deprecate_svg_embed_char_paths(value)

matplotlib.rcsetup.deprecate_svg_image_noscale(value)

matplotlib.rcsetup.update_savefig_format(value)

matplotlib.rcsetup.validate_animation_writer_path(p)

matplotlib.rcsetup.validate_any(s)

matplotlib.rcsetup.validate_anylist(s)

matplotlib.rcsetup.validate_aspect(s)

matplotlib.rcsetup.validate_axisbelow(s)

matplotlib.rcsetup.validate_backend(s)

matplotlib.rcsetup.validate_bbox(s)

matplotlib.rcsetup.validate_bool(b)
  Convert b to a boolean or raise

matplotlib.rcsetup.validate_bool_maybe_none(b)
  Convert b to a boolean or raise
matplotlib.rcsetup.validate_capstylelist(s)

matplotlib.rcsetup.validate_color(s)
    return a valid color arg
matplotlib.rcsetup.validate_color_for_prop_cycle(s)

matplotlib.rcsetup.validate_color_or_auto(s)

matplotlib.rcsetup.validate_color_or_inherit(s)
    return a valid color arg
matplotlib.rcsetup.validate_colorlist(s)
    return a list of colorspecs
matplotlib.rcsetup.validate_corner_mask(s)

matplotlib.rcsetup.validate_cycler(s)
    return a Cycler object from a string repr or the object itself
matplotlib.rcsetup.validate_dashlist(s)

matplotlib.rcsetup.validate_dpi(s)
    confirm s is string ‘figure’ or convert s to float or raise
matplotlib.rcsetup.validate_fillstylelist(s)

matplotlib.rcsetup.validate_float(s)
    convert s to float or raise
matplotlib.rcsetup.validate_float_or_None(s)
    convert s to float, None or raise
matplotlib.rcsetup.validate_floatlist(s)
    convert s to float or raise
matplotlib.rcsetup.validate_font_properties(s)

matplotlib.rcsetup.validate_fontsize(s)

matplotlib.rcsetup.validate_fontszelist(s)

matplotlib.rcsetup.validate_fonttype(s)
    confirm that this is a Postscript of PDF font type that we know how to convert to
matplotlib.rcsetup.validate_hatch(s)
    Validate a hatch pattern. A hatch pattern string can have any sequence of the following characters: \ / | - + * . x o 0.
Matplotlib, Release 2.0.0

matplotlib.rcsetup.validate_hatchlist(s)
    Validate a hatch pattern. A hatch pattern string can have any sequence of the following characters: \
    / | - + * . x o 0.

matplotlib.rcsetup.validate_hinting(s)

matplotlib.rcsetup.validate_hist_bins(s)

matplotlib.rcsetup.validate_int(s)
    convert s to int or raise

matplotlib.rcsetup.validate_int_or_None(s)
    if not None, tries to validate as an int

matplotlib.rcsetup.validate_joinstylelist(s)

matplotlib.rcsetup.validate_maskedarray(v)

matplotlib.rcsetup.validate_negative_linestyle_legacy(s)

class matplotlib.rcsetup.validate_nseq_float(n=None)
    Bases: object

class matplotlib.rcsetup.validate_nseq_int(n=None)
    Bases: object

matplotlib.rcsetup.validate_path_exists(s)
    If s is a path, return s, else False

matplotlib.rcsetup.validate_ps_distiller(s)

matplotlib.rcsetup.validate_sketch(s)

matplotlib.rcsetup.validate_string_or_None(s)
    convert s to string or raise

matplotlib.rcsetup.validate_stringlist(s)
    return a list

matplotlib.rcsetup.validatetkpythoninspect(s)

matplotlib.rcsetup.validate_toolbar(s)

matplotlib.rcsetup.validate_whiskers(s)
46.1 matplotlib.sankey

Module for creating Sankey diagrams using matplotlib

```python
class matplotlib.sankey.Sankey(ax=None, scale=1.0, unit='', format='%.G', gap=0.25, radius=0.1, shoulder=0.03, offset=0.15, head_angle=100, margin=0.4, tolerance=1e-06, **kwargs)
```

Bases: object

Sankey diagram in matplotlib

Sankey diagrams are a specific type of flow diagram, in which the width of the arrows is shown proportionally to the flow quantity. They are typically used to visualize energy or material or cost transfers between processes. Wikipedia (6/1/2011)

Create a new Sankey instance.

Optional keyword arguments:
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ax</td>
<td>axes onto which the data should be plotted If ax isn’t provided, new axes will be created.</td>
</tr>
<tr>
<td>scale</td>
<td>scaling factor for the flows scale sizes the width of the paths in order to maintain proper layout. The same scale is applied to all subdiagrams. The value should be chosen such that the product of the scale and the sum of the inputs is approximately 1.0 (and the product of the scale and the sum of the outputs is approximately -1.0).</td>
</tr>
<tr>
<td>unit</td>
<td>string representing the physical unit associated with the flow quantities If unit is None, then none of the quantities are labeled.</td>
</tr>
<tr>
<td>format</td>
<td>a Python number formatting string to be used in labeling the flow as a quantity (i.e., a number times a unit, where the unit is given)</td>
</tr>
<tr>
<td>gap</td>
<td>space between paths that break in/break away to/from the top or bottom</td>
</tr>
<tr>
<td>radius</td>
<td>inner radius of the vertical paths</td>
</tr>
<tr>
<td>shoulder</td>
<td>size of the shoulders of output arrowS</td>
</tr>
<tr>
<td>offset</td>
<td>text offset (from the dip or tip of the arrow)</td>
</tr>
<tr>
<td>head_angle</td>
<td>angle of the arrow heads (and negative of the angle of the tails) [deg]</td>
</tr>
<tr>
<td>margin</td>
<td>minimum space between Sankey outlines and the edge of the plot area</td>
</tr>
<tr>
<td>tolerance</td>
<td>acceptable maximum of the magnitude of the sum of flows The magnitude of the sum of connected flows cannot be greater than tolerance.</td>
</tr>
</tbody>
</table>

The optional arguments listed above are applied to all subdiagrams so that there is consistent alignment and formatting.

If Sankey is instantiated with any keyword arguments other than those explicitly listed above (**kwargs), they will be passed to add(), which will create the first subdiagram.

In order to draw a complex Sankey diagram, create an instance of Sankey by calling it without any kwargs:

```python
sankey = Sankey()
```

Then add simple Sankey sub-diagrams:

```python
sankey.add() # 1
sankey.add() # 2
#...
sankey.add() # n
```

Finally, create the full diagram:

```python
sankey.finish()
```

Or, instead, simply daisy-chain those calls:
Sankey().add().add... .add().finish()

See also:

add() finish()

Examples:

The default settings produce a diagram like this.
Flow Diagram of a Widget

Widget A

First 10%
Second 20%
Third 5%
Fourth 15%
Fifth 10%

Hurray! 40%

25%
60%
Add a simple Sankey diagram with flows at the same hierarchical level.

Return value is the instance of `Sankey`.

Optional keyword arguments:
<table>
<thead>
<tr>
<th>Key-word</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>patchlabel</td>
<td>label to be placed at the center of the diagram Note: label (not patchlabel) will be passed to the patch through **kwargs and can be used to create an entry in the legend.</td>
</tr>
<tr>
<td>flows</td>
<td>array of flow values By convention, inputs are positive and outputs are negative.</td>
</tr>
<tr>
<td>orientations</td>
<td>list of orientations of the paths Valid values are 1 (from/to the top), 0 (from/to the left or right), or -1 (from/to the bottom). If orientations == 0, inputs will break in from the left and outputs will break away to the right.</td>
</tr>
<tr>
<td>labels</td>
<td>list of specifications of the labels for the flows Each value may be None (no labels), ‘’ (just label the quantities), or a labeling string. If a single value is provided, it will be applied to all flows. If an entry is a non-empty string, then the quantity for the corresponding flow will be shown below the string. However, if the unit of the main diagram is None, then quantities are never shown, regardless of the value of this argument.</td>
</tr>
<tr>
<td>trunk-length</td>
<td>length between the bases of the input and output groups</td>
</tr>
<tr>
<td>pathlengths</td>
<td>list of lengths of the arrows before break-in or after break-away If a single value is given, then it will be applied to the first (inside) paths on the top and bottom, and the length of all other arrows will be justified accordingly. The pathlengths are not applied to the horizontal inputs and outputs.</td>
</tr>
<tr>
<td>prior</td>
<td>index of the prior diagram to which this diagram should be connected</td>
</tr>
<tr>
<td>connect</td>
<td>a (prior, this) tuple indexing the flow of the prior diagram and the flow of this diagram which should be connected If this is the first diagram or prior is None, connect will be ignored.</td>
</tr>
<tr>
<td>rotation</td>
<td>angle of rotation of the diagram [deg] rotation is ignored if this diagram is connected to an existing one (using prior and connect). The interpretation of the orientations argument will be rotated accordingly (e.g., if rotation == 90, an orientations entry of 1 means to/from the left).</td>
</tr>
</tbody>
</table>

Valid kwargs are `matplotlib.patches.PathPatch()` arguments:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agg_filter</td>
<td>unknown</td>
</tr>
<tr>
<td>alpha</td>
<td>float or None</td>
</tr>
<tr>
<td>animated</td>
<td>[True</td>
</tr>
<tr>
<td>antialiased</td>
<td>[True</td>
</tr>
<tr>
<td>axes</td>
<td>an Axes instance</td>
</tr>
<tr>
<td>capstyle</td>
<td>[‘butt’</td>
</tr>
<tr>
<td>clip_box</td>
<td>a <code>matplotlib.transforms.Bbox</code> instance</td>
</tr>
<tr>
<td>clip_on</td>
<td>[True</td>
</tr>
<tr>
<td>clip_path</td>
<td>[(Path, Transform)</td>
</tr>
<tr>
<td>color</td>
<td>matplotlib color spec</td>
</tr>
<tr>
<td>contains</td>
<td>a callable function</td>
</tr>
</tbody>
</table>

Continued on next page
As examples, `fill=False` and `label='A legend entry'`. By default, `facecolor='#bfd1d4'` (light blue) and `linewidth=0.5`.

The indexing parameters (`prior` and `connect`) are zero-based.

The flows are placed along the top of the diagram from the inside out in order of their index within the `flows` list or array. They are placed along the sides of the diagram from the top down and along the bottom from the outside in.

If the sum of the inputs and outputs is nonzero, the discrepancy will appear as a cubic Bezier curve along the top and bottom edges of the trunk.

47.1 matplotlib.scale

class matplotlib.scale.InvertedLog10Transform(shorthand_name=None)
    Bases: matplotlib.scale.InvertedLogTransformBase
    Creates a new TransformNode.
    shorthand_name - a string representing the “name” of this transform. The name carries no significance other than to improve the readability of str(transform) when DEBUG=True.
    base = 10.0

inverted()

class matplotlib.scale.InvertedLog2Transform(shorthand_name=None)
    Bases: matplotlib.scale.InvertedLogTransformBase
    Creates a new TransformNode.
    shorthand_name - a string representing the “name” of this transform. The name carries no significance other than to improve the readability of str(transform) when DEBUG=True.
    base = 2.0

inverted()

class matplotlib.scale.InvertedLogTransform(base)
    Bases: matplotlib.scale.InvertedLogTransformBase
    inverted()

class matplotlib.scale.InvertedLogTransformBase(shorthand_name=None)
    Bases: matplotlib.transforms.Transform
    Creates a new TransformNode.
shorthand_name - a string representing the “name” of this transform. The name carries no significance other than to improve the readability of str(transform) when DEBUG=True.

has_inverse = True

input_dims = 1

is_separable = True

output_dims = 1

transform_non_affine(a)

class matplotlib.scale.InvertedNaturalLogTransform(shorthand_name=None)
    Bases: matplotlib.scale.InvertedLogTransformBase

Creates a new TransformNode.

shorthand_name - a string representing the “name” of this transform. The name carries no significance other than to improve the readability of str(transform) when DEBUG=True.

base = 2.718281828459045

inverted()

class matplotlib.scale.InvertedSymmetricalLogTransform(base, linthresh, linscale)
    Bases: matplotlib.transforms.Transform

has_inverse = True

input_dims = 1

inverted()

is_separable = True

output_dims = 1

transform_non_affine(a)

class matplotlib.scale.LinearScale(axis, **kwargs)
    Bases: matplotlib.scale.ScaleBase

The default linear scale.
The transform for linear scaling is just the \texttt{IdentityTransform}.

```python
get_transform()
```

name = ‘linear’

```python
set_default_locators_and_formatters(axis)
```

Set the locators and formatters to reasonable defaults for linear scaling.

```python
class matplotlib.scale.Log10Transform(nonpos)
Bases: matplotlib.scale.LogTransformBase

base = 10.0

inverted()
```

```python
class matplotlib.scale.Log2Transform(nonpos)
Bases: matplotlib.scale.LogTransformBase

base = 2.0

inverted()
```

```python
class matplotlib.scale.LogScale(axis, **kwargs)
Bases: matplotlib.scale.ScaleBase

A standard logarithmic scale. Care is taken so non-positive values are not plotted.

For computational efficiency (to push as much as possible to Numpy C code in the common cases), this scale provides different transforms depending on the base of the logarithm:

- base 10 (\texttt{Log10Transform})
- base 2 (\texttt{Log2Transform})
- base e (\texttt{NaturalLogTransform})
- arbitrary base (\texttt{LogTransform})

\texttt{basex/basey}: The base of the logarithm

\texttt{nonposx/nonposy}: [’mask’ | ‘clip’] non-positive values in \texttt{x} or \texttt{y} can be masked as invalid, or clipped to a very small positive number

\texttt{subsx/subsy}: Where to place the subticks between each major tick. Should be a sequence of integers.

For example, in a log10 scale: \[2, 3, 4, 5, 6, 7, 8, 9\]

will place 8 logarithmically spaced minor ticks between each major tick.

```python
class InvertedLog10Transform(shorthand_name=None)
Bases: matplotlib.scale.InvertedLogTransformBase

Creates a new TransformNode.
```
shorthand_name - a string representing the “name” of this transform. The name carries no significance other than to improve the readability of str(transform) when DEBUG=True.

base = 10.0

inverted()

class LogScale.InvertedLog2Transform(shorthand_name=None)
    Bases: matplotlib.scale.InvertedLogTransformBase
    Creates a new TransformNode.

class LogScale.LogTransform(base, nonpos):
    Bases: matplotlib.scale.LogTransformBase
    inverted()

class LogScale.LogTransformBase(nonpos):
    Bases: matplotlib.transforms.Transform
    has_inverse = True

    input_dims = 1

    is_separable = True

    output_dims = 1

    transform_non_affine(a)

class LogScale.NaturalLogTransform(nonpos):
    Bases: matplotlib.scale.LogTransformBase
    base = 2.718281828459045

    inverted()

LogScale.get_transform()
    Return a Transform instance appropriate for the given logarithm base.

LogScale.limit_range_for_scale(vmin, vmax, minpos)
    Limit the domain to positive values.

LogScale.name = 'log'

LogScale.set_default_locators_and_formatters(axis)
    Set the locators and formatters to specialized versions for log scaling.

class matplotlib.scale.LogTransform(base, nonpos):
    Bases: matplotlib.scale.LogTransformBase
    inverted()
class matplotlib.scale.LogTransformBase(nonpos)
    Bases: matplotlib.transforms.Transform
    has_inverse = True

    inverted()

    is_separable = True

    output_dims = 1

    transform_non_affine(a)
        logistic transform (base 10)

class matplotlib.scale.LogitScale(axis, nonpos='mask')
    Bases: matplotlib.scale.ScaleBase
    Logit scale for data between zero and one, both excluded.

    This scale is similar to a log scale close to zero and to one, and almost linear around 0.5. It maps the
    interval ]0, 1[ onto ]-infty, +infty[.

    nonpos: ['mask' | 'clip'] values beyond ]0, 1[ can be masked as invalid, or clipped to a number very
close to 0 or 1

    get_transform()
        Return a LogitTransform instance.

    limit_range_for_scale(vmin, vmax, minpos)
        Limit the domain to values between 0 and 1 (excluded).
name = 'logit'

set_default_locators_and_formatters(axis)

class matplotlib.scale.LogitTransform(nonpos)
    Bases: matplotlib.transforms.Transform
    has_inverse = True

    input_dims = 1

    inverted()

    is_separable = True

    output_dims = 1

    transform_non_affine(a)
        logit transform (base 10), masked or clipped

class matplotlib.scale.NaturalLogTransform(nonpos)
    Bases: matplotlib.scale.LogTransformBase

    base = 2.718281828459045

    inverted()

class matplotlib.scale.ScaleBase
    Bases: object
    The base class for all scales.
    Scales are separable transformations, working on a single dimension.
    Any subclasses will want to override:
        • name
        • get_transform()
        • set_default_locators_and_formatters()

    And optionally:
        • limit_range_for_scale()

    get_transform()
        Return the Transform object associated with this scale.
**limit_range_for_scale** *(vmin, vmax, minpos)*

Returns the range *vmin*, *vmax*, possibly limited to the domain supported by this scale.

*minpos should be the minimum positive value in the data.* This is used by log scales to determine a minimum value.

**set_default_locators_and_formatters**(axis)

Set the *Locator* and *Formatter* objects on the given axis to match this scale.

**class matplotlib.scale.SymmetricalLogScale**(axis, **kwargs)

Bases: matplotlib.scale.ScaleBase

The symmetrical logarithmic scale is logarithmic in both the positive and negative directions from the origin.

Since the values close to zero tend toward infinity, there is a need to have a range around zero that is linear. The parameter *linthresh* allows the user to specify the size of this range (*-linthresh*, *linthresh*).

*basex/basey:* The base of the logarithm

*linthreshx/linthreshy:* The range (-*x*, *x*) within which the plot is linear (to avoid having the plot go to infinity around zero).

*subsx/subsy:* Where to place the subticks between each major tick. Should be a sequence of integers. For example, in a log10 scale: [2, 3, 4, 5, 6, 7, 8, 9] will place 8 logarithmically spaced minor ticks between each major tick.

*linscalex/linscaley:* This allows the linear range (*-linthresh to linthresh*) to be stretched relative to the logarithmic range. Its value is the number of decades to use for each half of the linear range. For example, when *linscale* == 1.0 (the default), the space used for the positive and negative halves of the linear range will be equal to one decade in the logarithmic range.

**class InvertedSymmetricalLogTransform**(base, linthresh, linscale)

Bases: matplotlib.transforms.Transform

**has_inverse** = True

**input_dims** = 1

**inverted()**

**is_separable** = True

**output_dims** = 1

**transform_non_affine**(a)

**class SymmetricalLogScale.SymmetricalLogTransform**(base, linthresh, linscale)

Bases: matplotlib.transforms.Transform
has_inverse = True

input_dims = 1

inverted()

is_separable = True

output_dims = 1

transform_non_affine(a)

SymmetricalLogScale.get_transform()
    Return a SymmetricalLogTransform instance.
SymmetricalLogScale.name = 'symlog'

SymmetricalLogScale.set_default_locators_and_formatters(axis)
    Set the locators and formatters to specialized versions for symmetrical log scaling.

class matplotlib.scale.SymmetricalLogTransform(base, linthresh, linscale)
    Bases: matplotlib.transforms.Transform
has_inverse = True

input_dims = 1

inverted()

is_separable = True

output_dims = 1

transform_non_affine(a)

matplotlib.scale.get_scale_docs()
    Helper function for generating docstrings related to scales.
matplotlib.scale.get_scale_names()

matplotlib.scale.register_scale(scale_class)
    Register a new kind of scale.
scale_class must be a subclass of ScaleBase.

matplotlib.scale.scale_factory(scale, axis, **kwargs)
Return a scale class by name.

ACCEPTS: [ linear | log | logit | symlog ]
48.1 matplotlib.spines

```python
class matplotlib.spines.Spine(axes, spine_type, path, **kwargs)
    Bases: matplotlib.patches.Patch
    
an axis spine – the line noting the data area boundaries

    Spines are the lines connecting the axis tick marks and noting the boundaries of the data area. They
can be placed at arbitrary positions. See function: set_position for more information.

    The default position is ('outward', 0).

    Spines are subclasses of class: Patch, and inherit much of their behavior.

    Spines draw a line or a circle, depending if function: set_patch_line or func-
tion: set_patch_circle has been called. Line-like is the default.

    • axes : the Axes instance containing the spine
    • spine_type : a string specifying the spine type
    • path : the path instance used to draw the spine

    Valid kwargs are:

    Property | Description
    -------- | ------------
    agg_filter | unknown
    alpha | float or None
    animated | [True | False]
    antialiased or aa | [True | False] or None for default
    axes | an Axes instance
    capstyle | ['butt' | 'round' | 'projecting']
    clip_box | a matplotlib.transforms.Bbox instance
    clip_on | [True | False]
    clip_path | [(Path, Transform)| Patch | None]
    color | matplotlib color spec
    contains | a callable function
    edgecolor or ec | mpl color spec, None, 'none', or 'auto'
```

**classmethod circular_spine** *(axes, center, radius, **kwargs)*

Returns a circular Spine.

**cla()**
Clear the current spine

**draw**(artist, renderer, *args, **kwargs)

**get_bounds()**
Get the bounds of the spine.

**get_patch_transform()**

**get_path()**

**get_position()**
get the spine position

**get_smart_bounds()**
get whether the spine has smart bounds

**get_spine_transform()**
get the spine transform

**is_frame_like()**
return True if directly on axes frame
This is useful for determining if a spine is the edge of an old style MPL plot. If so, this function will return True.

**classmethod linear_spine(ax, spine_type, **kwargs)**

(statmethod) Returns a linear Spine.

**register_axis(ax)**

register an axis

An axis should be registered with its corresponding spine from the Axes instance. This allows the spine to clear any axis properties when needed.

**set_bounds(lower, upper)**

Set the bounds of the spine.

**set_color(c)**

Set the edgecolor.

ACCEPTS: matplotlib color arg or sequence of rgba tuples

See also:

**set_facecolor(), set_edgecolor()** For setting the edge or face color individually.

**set_patch_circle(center, radius)**

set the spine to be circular

**set_patch_line()**

set the spine to be linear

**set_position(position)**

set the position of the spine

Spine position is specified by a 2 tuple of (position type, amount). The position types are:

- 'outward': place the spine out from the data area by the specified number of points. (Negative values specify placing the spine inward.)
- 'axes': place the spine at the specified Axes coordinate (from 0.0-1.0).
- 'data': place the spine at the specified data coordinate.

Additionally, shorthand notations define a special positions:

- 'center' -> ('axes', 0.5)
- 'zero' -> ('data', 0.0)

**set_smart_bounds(value)**

set the spine and associated axis to have smart bounds
49.1 matplotlib.style

matplotlib.style.context(style, after_reset=False)

Context manager for using style settings temporarily.

**Parameters**

- **style** : str, dict, or list
  
  A style specification. Valid options are:
  
<table>
<thead>
<tr>
<th>str</th>
<th>The name of a style or a path/URL to a style file. For a list of available style names, see style.available.</th>
</tr>
</thead>
<tbody>
<tr>
<td>dict</td>
<td>Dictionary with valid key/value pairs for matplotlib.rcParams.</td>
</tr>
<tr>
<td>list</td>
<td>A list of style specifiers (str or dict) applied from first to last in the list.</td>
</tr>
</tbody>
</table>

- **after_reset** : bool
  
  If True, apply style after resetting settings to their defaults; otherwise, apply style on top of the current settings.

matplotlib.style.reload_library()

Reload style library.

matplotlib.style.use(style)

Use matplotlib style settings from a style specification.

The style name of ‘default’ is reserved for reverting back to the default style settings.

**Parameters**

- **style** : str, dict, or list
  
  A style specification. Valid options are:
  
<table>
<thead>
<tr>
<th>str</th>
<th>The name of a style or a path/URL to a style file. For a list of available style names, see style.available.</th>
</tr>
</thead>
<tbody>
<tr>
<td>dict</td>
<td>Dictionary with valid key/value pairs for matplotlib.rcParams.</td>
</tr>
<tr>
<td>list</td>
<td>A list of style specifiers (str or dict) applied from first to last in the list.</td>
</tr>
</tbody>
</table>

matplotlib.style.library

Dictionary of available styles
matplotlib.style.available

List of available styles
50.1 matplotlib.text

Classes for including text in a figure.

class matplotlib.text.Annotation(s, xy, xytext=None, xycoords='data', textcoords=None, arrowprops=None, annotation_clip=None, **kwargs)

Bases: matplotlib.text.Text, matplotlib.text._AnnotationBase

Annotate the point xy with text s.

Additional kwargs are passed to Text.

Parameters

s : str
    The text of the annotation

xy : iterable
    Length 2 sequence specifying the (x,y) point to annotate

xytext : iterable, optional
    Length 2 sequence specifying the (x,y) to place the text at. If None, defaults to xy.

xycoords : str, Artist, Transform, callable or tuple, optional
    The coordinate system that xy is given in.

For a str the allowed values are:
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘figure points’</td>
<td>points from the lower left of the figure</td>
</tr>
<tr>
<td>‘figure pixels’</td>
<td>pixels from the lower left of the figure</td>
</tr>
<tr>
<td>‘figure fraction’</td>
<td>fraction of figure from lower left</td>
</tr>
<tr>
<td>‘axes points’</td>
<td>points from lower left corner of axes</td>
</tr>
<tr>
<td>‘axes pixels’</td>
<td>pixels from lower left corner of axes</td>
</tr>
<tr>
<td>‘axes fraction’</td>
<td>fraction of axes from lower left</td>
</tr>
<tr>
<td>‘data’</td>
<td>use the coordinate system of the object being annotated (default)</td>
</tr>
<tr>
<td>‘polar’</td>
<td>(theta, r) if not native ‘data’ coordinates</td>
</tr>
</tbody>
</table>

If a `Artist` object is passed in the units are fraction if it’s bounding box.

If a `Transform` object is passed in use that to transform `xy` to screen coordinates

If a callable it must take a `RendererBase` object as input and return a `Transform` or `Bbox` object

If a tuple must be length 2 tuple of str, `Artist`, `Transform` or callable objects. The first transform is used for the x coordinate and the second for y.

See Advanced Annotation for more details.

Defaults to 'data'

textcoords: str, `Artist`, `Transform`, callable or tuple, optional

The coordinate system that `xytext` is given, which may be different than the coordinate system used for `xy`.

All `xycoords` values are valid as well as the following strings:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘offset points’</td>
<td>offset (in points) from the <code>xy</code> value</td>
</tr>
<tr>
<td>‘offset pixels’</td>
<td>offset (in pixels) from the <code>xy</code> value</td>
</tr>
</tbody>
</table>

defaults to the input of `xycoords`

arrowprops: dict, optional

If not None, properties used to draw a `FancyArrowPatch` arrow between `xy` and `xytext`.

If `arrowprops` does not contain the key 'arrowstyle' the allowed keys are:
The following table shows the available keys and their descriptions:

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>width</td>
<td>the width of the arrow in points</td>
</tr>
<tr>
<td>headwidth</td>
<td>the width of the base of the arrow head in points</td>
</tr>
<tr>
<td>headlength</td>
<td>the length of the arrow head in points</td>
</tr>
<tr>
<td>shrink</td>
<td>fraction of total length to 'shrink' from both ends</td>
</tr>
</tbody>
</table>

If the `arrowprops` contains the key 'arrowstyle' the above keys are forbidden. The allowed values of 'arrowstyle' are:

<table>
<thead>
<tr>
<th>Name</th>
<th>Attrs</th>
</tr>
</thead>
<tbody>
<tr>
<td>'-'</td>
<td>None</td>
</tr>
<tr>
<td>'-</td>
<td>&gt;'</td>
</tr>
<tr>
<td>'-['</td>
<td>widthB=1.0,lengthB=0.2,angleB=None</td>
</tr>
<tr>
<td>'</td>

</tr>
</tbody>
</table>

Defaults to None

**annotation_clip**: bool, optional

Controls the visibility of the annotation when it goes outside the axes area.

If `True`, the annotation will only be drawn when the `xy` is inside the axes. If `False`, the annotation will always be drawn regardless of its position.

The default is `None`, which behave as `True` only if `xycoords` is “data”.

**Returns** Annotation

**anncoords**
contains(event)

draw(artist, renderer, *args, **kwargs)
    Draw the Annotation object to the given renderer.

get_window_extent(renderer=None)
    Return a Bbox object bounding the text and arrow annotation, in display units.

    renderer defaults to the _renderer attribute of the text object. This is not assigned until the first 
    execution of draw(), so you must use this kwarg if you want to call get_window_extent() 
    prior to the first draw(). For getting web page regions, it is simpler to call the method after 
    saving the figure. The dpi used defaults to self.figure.dpi; the renderer dpi is irrelevant.

set_figure(fig)

update_positions(renderer)
    “Update the pixel positions of the annotated point and the text.

xyann

class matplotlib.text.OffsetFrom(artist, ref_coord, unit='points')
    Bases: object

Callable helper class for working with Annotation

    Parameters artist: Artist, BboxBase, or Transform

        The object to compute the offset from.

        ref_coord: length 2 sequence

            If artist is an Artist or BboxBase, this values is the location to of the 
            offset origin in fractions of the artist bounding box.

            If artist is a transform, the offset origin is the transform applied to this 
            value.

        unit: {'points, 'pixels'}

            The screen units to use (pixels or points) for the offset input.

get_unit()
    The unit for input to the transform used by __call__

set_unit(unit)
    The unit for input to the transform used by __call__

    Parameters unit: {'points', 'pixels'}

class matplotlib.text.Text(x=0, y=0, text='', color=None, verticalalignment='baseline',
    horizontalalignment='left', multialignment=None, fontproperties=None, rotation=None, linespacing=None, rotation_mode=None, usetex=None, wrap=False, **kwargs)
    Bases: matplotlib.artist.Artist
Handle storing and drawing of text in window or data coordinates.

Create a `Text` instance at $x, y$ with string `text`.

Valid kwargs are

contains(*mouseevent*)
Test whether the mouse event occurred in the patch.
In the case of text, a hit is true anywhere in the axis-aligned bounding-box containing the text.
Returns True or False.

draw(*artist, renderer, *args, **kwargs*)
Draws the Text object to the given renderer.

get_bbox_patch()  
Return the bbox Patch object. Returns None if the FancyBboxPatch is not made.

get_color()  
Return the color of the text

get_family()  
Return the list of font families used for font lookup

get_font_properties()  
alias for get_fontproperties

get_fontfamily()  
alias for get_family

get_fontname()  
alias for get_name

get_fontproperties()  
Return the FontProperties object

get_fontsize()  
alias for get_size

get_fontstretch()  
alias for get_stretch

get_fontstyle()  
alias for get_style

get_fontvariant()  
alias for get_variant

get_fontweight()  
alias for get_weight

get_ha()  
alias for get_horizontalalignment
get_horizontalalignment()
    Return the horizontal alignment as string. Will be one of ‘left’, ‘center’ or ‘right’.

get_name()
    Return the font name as string

get_position()
    Return the position of the text as a tuple (x, y)

get_prop_tup(renderer=None)
    Return a hashable tuple of properties.
    Not intended to be human readable, but useful for backends who want to cache derived information about text (e.g., layouts) and need to know if the text has changed.

get_rotation()
    return the text angle as float in degrees

get_rotation_mode()
    get text rotation mode

get_size()
    Return the font size as integer

get_stretch()
    Get the font stretch as a string or number

get_style()
    Return the font style as string

get_text()
    Get the text as string

get_unitless_position()
    Return the unitless position of the text as a tuple (x, y)

get_usetex()
    Return whether this Text object will render using TeX.
    If the user has not manually set this value, it will default to the value of rcParams['text.usetex']

get_va()
    alias for getverticalalignment()

get_variant()
    Return the font variant as a string

get_verticalalignment()
    Return the vertical alignment as string. Will be one of ‘top’, ‘center’, ‘bottom’ or ‘baseline’.

get_weight()
    Get the font weight as string or number

get_window_extent(renderer=None, dpi=None)
    Return a Bbox object bounding the text, in display units.
In addition to being used internally, this is useful for specifying clickable regions in a png file on a web page.

`renderer` defaults to the `_renderer` attribute of the text object. This is not assigned until the first execution of `draw()`, so you must use this kwarg if you want to call `get_window_extent()` prior to the first `draw()`. For getting web page regions, it is simpler to call the method after saving the figure.

`dpi` defaults to `self.figure.dpi`; the renderer dpi is irrelevant. For the web application, if `figure.dpi` is not the value used when saving the figure, then the value that was used must be specified as the `dpi` argument.

`get_wrap()`
Returns the wrapping state for the text.

`static is_math_text(s, usetex=None)`
Returns a cleaned string and a boolean flag. The flag indicates if the given string `s` contains any mathtext, determined by counting unescaped dollar signs. If no mathtext is present, the cleaned string has its dollar signs unescaped. If `usetex` is on, the flag always has the value “TeX”.

`set_backgroundcolor(color)`
Set the background color of the text by updating the bbox.

See also:

`set_bbox()` To change the position of the bounding box.

ACCEPTS: any matplotlib color

`set_bbox(rectprops)`
Draw a bounding box around self. `rectprops` are any settable properties for a FancyBboxPatch, e.g., `facecolor='red', alpha=0.5`.

```python
t.set_bbox(dict(facecolor='red', alpha=0.5))
```

The default boxstyle is ‘square’. The mutation scale of the FancyBboxPatch is set to the fontsize.

ACCEPTS: FancyBboxPatch prop dict

`set_clip_box(clipbox)`
Set the artist’s clip `Bbox`.

ACCEPTS: a `matplotlib.transforms.Bbox` instance

`set_clip_on(b)`
Set whether artist uses clipping.

When False artists will be visible out side of the axes which can lead to unexpected results.

ACCEPTS: [True | False]

`set_clip_path(path, transform=None)`
Set the artist’s clip path, which may be:

- a `Patch` (or subclass) instance
• a Path instance, in which case an optional Transform instance may be provided, which
will be applied to the path before using it for clipping.

• None, to remove the clipping path

For efficiency, if the path happens to be an axis-aligned rectangle, this method will set the clip-
ping box to the corresponding rectangle and set the clipping path to None.

ACCEPTS: [ (Path, Transform) | Patch | None ]

set_color(color)
Set the foreground color of the text

ACCEPTS: any matplotlib color

set_family(fontname)
Set the font family. May be either a single string, or a list of strings in decreasing priority. Each
string may be either a real font name or a generic font class name. If the latter, the specific font
names will be looked up in the matplotlibrc file.

ACCEPTS: [FONTNAME | ‘serif’ | ‘sans-serif’ | ‘cursive’ | ‘fantasy’ | ‘monospace’ ]

set_font_properties(fp)
alias for set_fontproperties

set_fontname(fontname)
alias for set_family

set_fontproperties(fp)
Set the font properties that control the text. fp must be a matplotlib.font_manager.
FontProperties object.

ACCEPTS: a matplotlib.font_manager.FontProperties instance

set_fontsize(fontsize)
alias for set_size

set_fontstretch(stretch)
alias for set_stretch

set_fontstyle(fontstyle)
alias for set_style

set_fontvariant(variant)
alias for set_variant

set_fontweight(weight)
alias for set_weight

set_ha(align)
alias for set_horizontalalignment

set_horizontalalignment(align)
Set the horizontal alignment to one of

ACCEPTS: [ ‘center’ | ‘right’ | ‘left’ ]
**set_linespacing***(spacing)*
Set the line spacing as a multiple of the font size. Default is 1.2.

**ACCEPTS:** float (multiple of font size)

**set_ma**(align)
alias for set_verticalalignment

**set_multialignment**(align)
Set the alignment for multiple lines layout. The layout of the bounding box of all the lines is
determined by the horizontalalignment and verticalalignment properties, but the multiline text
within that box can be

**ACCEPTS:** ['left' | ‘right’ | ‘center’ ]

**set_name**(fontname)
alias for set_family

**set_position**(xy)
Set the (x, y) position of the text

**ACCEPTS:** (x,y)

**set_rotation**(s)
Set the rotation of the text

**ACCEPTS:** [ angle in degrees | ‘vertical’ | ‘horizontal’ ]

**set_rotation_mode**(m)
set text rotation mode. If “anchor”, the un-rotated text will first aligned according to their ha and
va, and then will be rotated with the alignment reference point as a origin. If None (default),
the text will be rotated first then will be aligned.

**set_size**(fontsize)
Set the font size. May be either a size string, relative to the default font size, or an absolute font
size in points.

**ACCEPTS:** [size in points | ‘xx-small’ | ‘x-small’ | ‘small’ | ‘medium’ | ‘large’ | ‘x-large’ | ‘xx-large’ ]

**set_stretch**(stretch)
Set the font stretch (horizontal condensation or expansion).

**ACCEPTS:** [a numeric value in range 0-1000 | ‘ultra-condensed’ | ‘extra-condensed’ | ‘condensed’ | ‘semi-condensed’ | ‘normal’ | ‘semi-expanded’ | ‘expanded’ | ‘extra-expanded’ | ‘ultra-expanded’ ]

**set_style**(fontstyle)
Set the font style.

**ACCEPTS:** [ ‘normal’ | ‘italic’ | ‘oblique’ ]

**set_text**(s)
Set the text string s

It may contain newlines (\n) or math in LaTeX syntax.
ACCEPTS: string or anything printable with ‘%s’ conversion.

set_usetex(usetex)
    Set this Text object to render using TeX (or not).
    If None is given, the option will be reset to use the value of rcParams['text.usetex']

set_va(align)
    alias for set_verticalalignment

set_variant(variant)
    Set the font variant, either ‘normal’ or ‘small-caps’.
    ACCEPTS: [‘normal’ | ‘small-caps’ ]

set_verticalalignment(align)
    Set the vertical alignment
    ACCEPTS: [‘center’ | ‘top’ | ‘bottom’ | ‘baseline’ ]

set_weight(weight)
    Set the font weight.

set_wrap(wrap)
    Sets the wrapping state for the text.

set_x(x)
    Set the x position of the text
    ACCEPTS: float

set_y(y)
    Set the y position of the text
    ACCEPTS: float

update(kwarg)
    Update properties from a dictionary.

update_bbox_position_size(renderer)
    Update the location and the size of the bbox. This method should be used when the position and size of the bbox needs to be updated before actually drawing the bbox.

update_from(other)
    Copy properties from other to self

zorder = 3
class matplotlib.text.TextWithDash(x=0, y=0, text='', color=None, verticalalignment='center', horizontalalignment='center', multialignment=None, fontproperties=None, rotation=None, linespacing=None, dashlength=0.0, dashdirection=0, dashrotation=None, dashpad=3, dashpush=0)

Bases: matplotlib.text.Text

This is basically a Text with a dash (drawn with a Line2D) before/after it. It is intended to be a drop-in replacement for Text, and should behave identically to it when dashlength = 0.0.

The dash always comes between the point specified by set_position() and the text. When a dash exists, the text alignment arguments (horizontalalignment, verticalalignment) are ignored.

dashlength is the length of the dash in canvas units. (default = 0.0).

dashdirection is one of 0 or 1, where 0 draws the dash after the text and 1 before. (default = 0).

dashrotation specifies the rotation of the dash, and should generally stay None. In this case get_dashrotation() returns get_rotation(). (i.e., the dash takes its rotation from the text’s rotation). Because the text center is projected onto the dash, major deviations in the rotation cause what may be considered visually unappealing results. (default = None)

dashpad is a padding length to add (or subtract) space between the text and the dash, in canvas units. (default = 3)

dashpush “pushes” the dash and text away from the point specified by set_position() by the amount in canvas units. (default = 0)

---

**Note:** The alignment of the two objects is based on the bounding box of the Text, as obtained by get_window_extent(). This, in turn, appears to depend on the font metrics as given by the rendering backend. Hence the quality of the “centering” of the label text with respect to the dash varies depending on the backend used.

---

**Note:** I’m not sure that I got the get_window_extent() right, or whether that’s sufficient for providing the object bounding box.

---

draw(renderer)

Draw the TextWithDash object to the given renderer.

get_dashdirection()

Get the direction dash. 1 is before the text and 0 is after.

get_dashlength()

Get the length of the dash.

get_dashpad()

Get the extra spacing between the dash and the text, in canvas units.

get_dashpush()

Get the extra spacing between the dash and the specified text position, in canvas units.
get dashrotation()
Get the rotation of the dash in degrees.

get figure()
return the figure instance the artist belongs to

get position()
Return the position of the text as a tuple (x, y)

get prop_tup(renderer=None)
Return a hashable tuple of properties.
Not intended to be human readable, but useful for backends who want to cache derived information about text (e.g., layouts) and need to know if the text has changed.

get unitless position()
Return the unitless position of the text as a tuple (x, y)

get window_extent(renderer=None)
Return a Bbox object bounding the text, in display units.
In addition to being used internally, this is useful for specifying clickable regions in a png file on a web page.

renderer defaults to the _renderer attribute of the text object. This is not assigned until the first execution of draw(), so you must use this kwarg if you want to call get_window_extent() prior to the first draw(). For getting web page regions, it is simpler to call the method after saving the figure.

set dashdirection(dd)
Set the direction of the dash following the text. 1 is before the text and 0 is after. The default is 0, which is what you’d want for the typical case of ticks below and on the left of the figure.

ACCEPTS: int (1 is before, 0 is after)

set dashlength(dl)
Set the length of the dash.

ACCEPTS: float (canvas units)

set dashpad(dp)
Set the “pad” of the TextWithDash, which is the extra spacing between the dash and the text, in canvas units.

ACCEPTS: float (canvas units)

set dashpush(dp)
Set the “push” of the TextWithDash, which is the extra spacing between the beginning of the dash and the specified position.

ACCEPTS: float (canvas units)

set dashrotation(dr)
Set the rotation of the dash, in degrees

ACCEPTS: float (degrees)
**set_figure(fig)**
Set the figure instance the artist belong to.

ACCEPTS: a *matplotlib.figure.Figure* instance

**set_position(xy)**
Set the (x, y) position of the *TextWithDash*.

ACCEPTS: (x, y)

**set_transform(t)**
Set the *matplotlib.transforms.Transform* instance used by this artist.

ACCEPTS: a *matplotlib.transforms.Transform* instance

**set_x(x)**
Set the x position of the *TextWithDash*.

ACCEPTS: float

**set_y(y)**
Set the y position of the *TextWithDash*.

ACCEPTS: float

**update_coords(renderer)**
Computes the actual x, y coordinates for text based on the input x, y and the *dashlength*. Since the rotation is with respect to the actual canvas’s coordinates we need to map back and forth.

**matplotlib.text.get_rotation(rotation)**
Return the text angle as float. The returned angle is between 0 and 360 deg.

*rotation* may be ‘horizontal’, ‘vertical’, or a numeric value in degrees.
51.1 matplotlib.ticker

51.1.1 Tick locating and formatting

This module contains classes to support completely configurable tick locating and formatting. Although the locators know nothing about major or minor ticks, they are used by the Axis class to support major and minor tick locating and formatting. Generic tick locators and formatters are provided, as well as domain specific custom ones.

Default Formatter

The default formatter identifies when the x-data being plotted is a small range on top of a large offset. To reduce the chances that the ticklabels overlap the ticks are labeled as deltas from a fixed offset. For example:

```python
ax.plot(np.arange(2000, 2010), range(10))
```

will have tick of 0-9 with an offset of +2e3. If this is not desired turn off the use of the offset on the default formatter:

```python
ax.get_xaxis().get_major_formatter().set_useOffset(False)
```

set the rcParam `axes.formatter.useoffset=False` to turn it off globally, or set a different formatter.

Tick locating

The Locator class is the base class for all tick locators. The locators handle autoscaling of the view limits based on the data limits, and the choosing of tick locations. A useful semi-automatic tick locator is MultipleLocator. You initialize this with a base, e.g., 10, and it picks axis limits and ticks that are multiples of your base.

The Locator subclasses defined here are

- **NullLocator**  No ticks
- **FixedLocator**  Tick locations are fixed
**IndexLocator**  locator for index plots (e.g., where \( x = \text{range}(\text{len}(y)) \))

**LinearLocator**  evenly spaced ticks from min to max

**LogLocator**  logarithmically ticks from min to max

**SymmetricalLogLocator**  locator for use with with the symlog norm, works like the LogLocator for the part outside of the threshold and add 0 if inside the limits

**MultipleLocator**

ticks and range are a multiple of base;  either integer or float

**OldAutoLocator**  choose a MultipleLocator and dynamically reassign it for intelligent ticking during navigation

**MaxNLocator**  finds up to a max number of ticks at nice locations

**AutoLocator**, **MaxNLocator**  with simple defaults. This is the default tick locator for most plotting.

**AutoMinorLocator**  locator for minor ticks when the axis is linear and the major ticks are uniformly spaced. It subdivides the major tick interval into a specified number of minor intervals, defaulting to 4 or 5 depending on the major interval.

**LogitLocator**  Locator for logit scaling.

There are a number of locators specialized for date locations - see the dates module

You can define your own locator by deriving from Locator. You must override the \(___call__\) method, which returns a sequence of locations, and you will probably want to override the autoscale method to set the view limits from the data limits.

If you want to override the default locator, use one of the above or a custom locator and pass it to the x or y axis instance. The relevant methods are:

```python
ax.xaxis.set_major_locator( xmajorLocator )
ax.xaxis.set_minor_locator( xminorLocator )
ax.yaxis.set_major_locator( ymajorLocator )
ax.yaxis.set_minor_locator( yminorLocator )
```

The default minor locator is the NullLocator, e.g., no minor ticks on by default.

**Tick formatting**

Tick formatting is controlled by classes derived from Formatter. The formatter operates on a single tick value and returns a string to the axis.

**NullFormatter**  No labels on the ticks

**IndexFormatter**  Set the strings from a list of labels

**FixedFormatter**  Set the strings manually for the labels

**FuncFormatter**  User defined function sets the labels

**StrMethodFormatter**  Use string format method
**FormatStrFormatter**  Use an old-style sprintf format string

**ScalarFormatter**  Default formatter for scalars: autopick the format string

**LogFormatter**  Formatter for log axes

**LogFormatterExponent**  Format values for log axis using $\text{exponent} = \log_{\text{base}}(\text{value})$.

**LogFormatterMathtext**  Format values for log axis using $\text{exponent} = \log_{\text{base}}(\text{value})$ using Math text.

**LogFormatterSciNotation**  Format values for log axis using scientific notation.

**LogitFormatter**  Probability formatter.

You can derive your own formatter from the Formatter base class by simply overriding the `__call__` method. The formatter class has access to the axis view and data limits.

To control the major and minor tick label formats, use one of the following methods:

```python
ax.xaxis.set_major_formatter( xmajorFormatter )
ax.xaxis.set_minor_formatter( xminorFormatter )
ax.yaxis.set_major_formatter( ymajorFormatter )
ax.yaxis.set_minor_formatter( yminorFormatter )
```

See *pylab_examples* example code: *major_minor_demo1.py* for an example of setting major and minor ticks. See the *matplotlib.dates* module for more information and examples of using date locators and formatters.

class matplotlib.ticker.TickHelper
   Bases: object

   axis = None

   create_dummy_axis(**kwargs)

   set_axis(axis)

   set_bounds(vmin, vmax)

   set_data_interval(vmin, vmax)

   set_view_interval(vmin, vmax)

class matplotlib.ticker.Formatter
   Bases: matplotlib.ticker.TickHelper

   Create a string based on a tick value and location.
fix_minus(s)
Some classes may want to replace a hyphen for minus with the proper unicode symbol (U+2212) for typographical correctness. The default is to not replace it.

Note, if you use this method, e.g., in format_data() or call, you probably don’t want to use it for format_data_short() since the toolbar uses this for interactive coord reporting and I doubt we can expect GUIs across platforms will handle the unicode correctly. So for now the classes that override fix_minus() should have an explicit format_data_short() method.

format_data(value)
Returns the full string representation of the value with the position unspecified.

format_data_short(value)
Return a short string version of the tick value.
Defaults to the position-independent long value.

get_offset()

locs = []

set_locs(locs)

class matplotlib.ticker.FixedFormatter(seq)
    Bases: matplotlib.ticker.Formatter
    Return fixed strings for tick labels based only on position, not value.
    Set the sequence of strings that will be used for labels.
    get_offset()

    set_offset_string(ofs)

class matplotlib.ticker.NullFormatter
    Bases: matplotlib.ticker.Formatter
    Always return the empty string.

class matplotlib.ticker.FuncFormatter(func)
    Bases: matplotlib.ticker.Formatter
    Use a user-defined function for formatting.
    The function should take in two inputs (a tick value x and a position pos), and return a string containing the corresponding tick label.

class matplotlib.ticker.FormatStrFormatter(fmt)
    Bases: matplotlib.ticker.Formatter
    Use an old-style (‘%’ operator) format string to format the tick.
The format string should have a single variable format (%) in it. It will be applied to the value (not the position) of the tick.

```python
class matplotlib.ticker.StrMethodFormatter(fmt)
Bases: matplotlib.ticker.Formatter

Use a new-style format string (as used by str.format()) to format the tick.

The field used for the value must be labeled `x` and the field used for the position must be labeled `pos`.
```

```python
class matplotlib.ticker.ScalarFormatter(useOffset=None, useMathText=None, useLocale=None)
Bases: matplotlib.ticker.Formatter

Format tick values as a number.

Tick value is interpreted as a plain old number. If useOffset==True and the data range is much smaller than the data average, then an offset will be determined such that the tick labels are meaningful. Scientific notation is used for data < 10^-n or data >= 10^m, where n and m are the power limits set using set_powerlimits((n,m)). The defaults for these are controlled by the axes. formatter.limits rc parameter.
```

```python
fix_minus(s)
  Replace hyphens with a unicode minus.

format_data(value)
  Return a formatted string representation of a number.

format_data_short(value)
  Return a short formatted string representation of a number.

get_offset()
  Return scientific notation, plus offset.

get_useLocale()

get_useOffset()

pprint_val(x)

set_locs(locs)
  Set the locations of the ticks.

set_powerlimits(lims)
  Sets size thresholds for scientific notation.

  lims is a two-element sequence containing the powers of 10 that determine the switchover threshold. Numbers below 10**lims[0] and above 10**lims[1] will be displayed in scientific notation.

  For example, formatter.set_powerlimits((-3, 4)) sets the pre-2007 default in which scientific notation is used for numbers less than 1e-3 or greater than 1e4.

See also:
```

51.1. matplotlib.ticker
Method `set_scientific()`

```
set_scientific(b)
```

Turn scientific notation on or off.

Method `set_powerlimits()`

```
set_useLocale(val)
```

```
set_useOffset(val)
```

```
useLocale
```

```
useOffset
```

class `matplotlib.ticker.LogFormatter`

```
base=10.0, labelOnlyBase=False, minor_thresholds=None, linthresh=None
```

Bases: `matplotlib.ticker.Formatter`

Base class for formatting ticks on a log or symlog scale.

It may be instantiated directly, or subclassed.

**Parameters**

`base` : float, optional, default: 10.

Base of the logarithm used in all calculations.

`labelOnlyBase` : bool, optional, default: False

If True, label ticks only at integer powers of base. This is normally True for major ticks and False for minor ticks.

`minor_thresholds` : (subset, all), optional, default: (1, 0.4)

If labelOnlyBase is False, these two numbers control the labeling of ticks that are not at integer powers of base; normally these are the minor ticks. The controlling parameter is the log of the axis data range. In the typical case where base is 10 it is the number of decades spanned by the axis, so we can call it `numdec`. If `numdec <= all`, all minor ticks will be labeled. If `all < numdec <= subset`, then only a subset of minor ticks will be labeled, so as to avoid crowding. If `numdec > subset` then no minor ticks will be labeled.

`linthresh` : None or float, optional, default: None

If a symmetric log scale is in use, its `linthresh` parameter must be supplied here.
Notes

The `set_locs` method must be called to enable the subsetting logic controlled by the `minor_thresholds` parameter.

In some cases such as the colorbar, there is no distinction between major and minor ticks; the tick locations might be set manually, or by a locator that puts ticks at integer powers of base and at intermediate locations. For this situation, disable the `minor_thresholds` logic by using `minor_thresholds=(np.inf, np.inf)`, so that all ticks will be labeled.

To disable labeling of minor ticks when ‘labelOnlyBase’ is False, use `minor_thresholds=(0, 0)`. This is the default for the “classic” style.

Examples

To label a subset of minor ticks when the view limits span up to 2 decades, and all of the ticks when zoomed in to 0.5 decades or less, use `minor_thresholds=(2, 0.5)`.

To label all minor ticks when the view limits span up to 1.5 decades, use `minor_thresholds=(1.5, 1.5)`.

`base` *(base)*

change the base for labeling.

```python
Warning: Should always match the base used for LogLocator
```

`format_data(value)`

`format_data_short(value)`

Return a short formatted string representation of a number.

`label_minor(labelOnlyBase)`

Switch minor tick labeling on or off.

Parameters `labelOnlyBase` : bool

If True, label ticks only at integer powers of base.

`pprint_val(x, d)`

`set_locs(locs=None)`

Use axis view limits to control which ticks are labeled.

The `locs` parameter is ignored in the present algorithm.

```python
class matplotlib.ticker.LogFormatterExponent(base=10.0, labelOnlyBase=False, minor_thresholds=None, linthresh=None)
```

Bases: `matplotlib.ticker.LogFormatter`

Format values for log axis using `exponent = log_base(value)`.
class matplotlib.ticker.LogFormatterMathtext(base=10.0, labelOnlyBase=False, minor_thresholds=None, linthresh=None)

    Format values for log axis using $\text{exponent} = \log_{\text{base}}(\text{value})$.

class matplotlib.ticker.Locator

    Bases: matplotlib.ticker.TickHelper

    Determine the tick locations;

    Note, you should not use the same locator between different $\text{Axis}$ because the locator stores references to the $\text{Axis}$ data and view limits.

    MAXTICKS = 1000

    autoscale()

        autoscale the view limits

    pan(numsteps)

        Pan numticks (can be positive or negative)

    raise_if_exceeds(locs)

        raise a RuntimeError if Locator attempts to create more than MAXTICKS locs

    refresh()

        refresh internal information based on current lim

    set_params(**kwargs)

        Do nothing, and raise a warning. Any locator class not supporting the set_params() function will call this.

    tick_values(vmin, vmax)

        Return the values of the located ticks given vmin and vmax.

    view_limits(vmin, vmax)

        select a scale for the range from vmin to vmax

        Normally this method is overridden by subclasses to change locator behaviour.

    zoom(direction)

        Zoom in/out on axis; if direction is >0 zoom in, else zoom out

class matplotlib.ticker.IndexLocator(base, offset)

    Bases: matplotlib.ticker.Locator
Place a tick on every multiple of some base number of points plotted, e.g., on every 5th point. It is assumed that you are doing index plotting; i.e., the axis is 0, len(data). This is mainly useful for x ticks.

place ticks on the i-th data points where (i-offset)%base==0

```
set_params(base=None, offset=None)
```
Set parameters within this locator

```
tick_values(vmin, vmax)
```

```
class matplotlib.ticker.FixedLocator(locs, nbins=None)
```
Bases: `matplotlib.ticker.Locator`

Tick locations are fixed. If nbins is not None, the array of possible positions will be subsampled to keep the number of ticks <= nbins +1. The subsampling will be done so as to include the smallest absolute value; for example, if zero is included in the array of possibilities, then it is guaranteed to be one of the chosen ticks.

```
set_params(nbins=None)
```
Set parameters within this locator.

```
tick_values(vmin, vmax)
```
” Return the locations of the ticks.

Note: Because the values are fixed, vmin and vmax are not used in this method.

```
class matplotlib.ticker.NullLocator
```
Bases: `matplotlib.ticker.Locator`

No ticks

```
tick_values(vmin, vmax)
```
” Return the locations of the ticks.

Note: Because the values are Null, vmin and vmax are not used in this method.

```
class matplotlib.ticker.LinearLocator(numticks=None, presets=None)
```
Bases: `matplotlib.ticker.Locator`

Determine the tick locations

The first time this function is called it will try to set the number of ticks to make a nice tick partitioning. Thereafter the number of ticks will be fixed so that interactive navigation will be nice

Use presets to set locs based on lom. A dict mapping vmin, vmax->locs

```
set_params(numticks=None, presets=None)
```
Set parameters within this locator.

```
tick_values(vmin, vmax)
```

view_limits(vmin, vmax)
Try to choose the view limits intelligently

class matplotlib.ticker.LogLocator(base=10.0, subs=(1.0,), numdecimals=4, numticks=None)
Bases: matplotlib.ticker.Locator

Determine the tick locations for log axes

Place ticks on the locations : subs[j] * base**i

Parameters

subs : None, string, or sequence of float, optional, default (1.0,)
Gives the multiples of integer powers of the base at which to place ticks. The default places ticks only at integer powers of the base. The permitted string values are 'auto' and 'all', both of which use an algorithm based on the axis view limits to determine whether and how to put ticks between integer powers of the base. With 'auto', ticks are placed only between integer powers; with 'all', the integer powers are included. A value of None is equivalent to 'auto'.

base(base)
set the base of the log scaling (major tick every base**i, i integer)

nonsingular(vmin, vmax)

set_params(base=None, subs=None, numdecimals=None, numticks=None)
Set parameters within this locator.

subs(subs)
set the minor ticks for the log scaling every base**i*subs[j]

tick_values(vmin, vmax)

view_limits(vmin, vmax)
Try to choose the view limits intelligently

class matplotlib.ticker.AutoLocator
Bases: matplotlib.ticker.MaxNLocator

class matplotlib.ticker.MultipleLocator(base=1.0)
Bases: matplotlib.ticker.Locator

Set a tick on every integer that is multiple of base in the view interval

set_params(base)
Set parameters within this locator.

tick_values(vmin, vmax)

view_limits(dmin, dmax)
Set the view limits to the nearest multiples of base that contain the data

class matplotlib.ticker.MaxNLocator(*args, **kwargs)
Bases: matplotlib.ticker.Locator
Select no more than N intervals at nice locations.

Keyword args:

nbins Maximum number of intervals; one less than max number of ticks. If the string 'auto', the number of bins will be automatically determined based on the length of the axis.

steps Sequence of nice numbers starting with 1 and ending with 10; e.g., [1, 2, 4, 5, 10]

integer If True, ticks will take only integer values, provided at least min_n_ticks integers are found within the view limits.

symmetric If True, autoscaling will result in a range symmetric about zero.

prune ['lower' | 'upper' | 'both' | None] Remove edge ticks – useful for stacked or ganged plots where the upper tick of one axes overlaps with the lower tick of the axes above it, primarily when rcParams['axes.autolimit_mode'] is 'round_numbers'. If prune='lower', the smallest tick will be removed. If prune='upper', the largest tick will be removed. If prune='both', the largest and smallest ticks will be removed. If prune=None, no ticks will be removed.

min_n_ticks Relax nbins and integer constraints if necessary to obtain this minimum number of ticks.

bin_boundaries(vmin, vmax)

Deprecated since version 2.0: The bin_boundaries function was deprecated in version 2.0.

default_params = {'nbins': 10, 'steps': None, 'integer': False, 'symmetric': False, 'prune': None, 'min_n_ticks': 2}

set_params(**kwargs)

Set parameters within this locator.

tick_values(vmin, vmax)

view_limits(dmin, dmax)

class matplotlib.ticker.AutoMinorLocator(n=None)

Bases: matplotlib.ticker.Locator

Dynamically find minor tick positions based on the positions of major ticks. Assumes the scale is linear and major ticks are evenly spaced.

n is the number of subdivisions of the interval between major ticks; e.g., n=2 will place a single minor tick midway between major ticks.

If n is omitted or None, it will be set to 5 or 4.

tick_values(vmin, vmax)

class matplotlib.ticker.SymmetricalLogLocator(transform=None, subs=None, linthresh=None, base=None)

Bases: matplotlib.ticker.Locator
Determine the tick locations for symmetric log axes

place ticks on the location= base**i*subs[j]

**set_params**(sub=\texttt{None}, numticks=\texttt{None})

Set parameters within this locator.

**tick_values**(vmin, vmax)

**view_limits**(vmin, vmax)

Try to choose the view limits intelligently
52.1 matplotlib.tight_layout

This module provides routines to adjust subplot params so that subplots are nicely fit in the figure. In doing so, only axis labels, tick labels, axes titles and offsetboxes that are anchored to axes are currently considered.

Internally, it assumes that the margins (left_margin, etc.) which are differences between ax.get_tightbbox and ax.bbox are independent of axes position. This may fail if Axes.adjustable is datalim. Also, This will fail for some cases (for example, left or right margin is affected by xlabel).

**matplotlib.tight_layout.auto_adjust_subplotpars(fig, renderer, nrows_ncols, num1num2_list, subplot_list, ax_bbox_list=None, pad=1.08, h_pad=None, w_pad=None, rect=None)**

Return a dictionary of subplot parameters so that spacing between subplots are adjusted. Note that this function ignore geometry information of subplot itself, but uses what is given by nrows_ncols and num1num2_list parameteres. Also, the results could be incorrect if some subplots have adjustable=datalim.

Parameters:

- **nrows_ncols** number of rows and number of columns of the grid.
- **num1num2_list** list of numbers specifying the area occupied by the subplot
- **subplot_list** list of subplots that will be used to calculate optimal subplot_params.
- **pad** [float] padding between the figure edge and the edges of subplots, as a fraction of the font-size.
- **h_pad, w_pad** [float]
  - padding (height/width) between edges of adjacent subplots. Defaults to pad_inches.
- **rect** [left, bottom, right, top] in normalized (0, 1) figure coordinates.

**matplotlib.tight_layout.get_renderer(fig)**

**matplotlib.tight_layout.get_subplotspec_list(axes_list, grid_spec=None)**

Return a list of subplotspec from the given list of axes. For an instance of axes that does not support subplotspec, None is inserted in the list.
If grid_spec is given, None is inserted for those not from the given grid_spec.

```python
matplotlib.tight_layout.get_tight_layout_figure(fig, axes_list, subplotspec_list, renderer, pad=1.08, h_pad=None, w_pad=None, rect=None)
```

Return subplot parameters for tight-layouted-figure with specified padding.

Parameters:

- `fig` : figure instance
- `axes_list` : a list of axes
- `subplotspec_list` : a list of subplotspec associated with each axes in axes_list
- `renderer` : renderer instance
- `pad` : [float] padding between the figure edge and the edges of subplots, as a fraction of the font-size.
- `h_pad, w_pad` : [float] padding (height/width) between edges of adjacent subplots. Defaults to pad_inches.
- `rect` : [if rect is given, it is interpreted as a rectangle] (left, bottom, right, top) in the normalized figure coordinate that the whole subplots area (including labels) will fit into. Default is (0, 0, 1, 1).
53.1 matplotlib.transforms

matplotlib includes a framework for arbitrary geometric transformations that is used determine the final position of all elements drawn on the canvas.

Transforms are composed into trees of TransformNode objects whose actual value depends on their children. When the contents of children change, their parents are automatically invalidated. The next time an invalidated transform is accessed, it is recomputed to reflect those changes. This invalidation/caching approach prevents unnecessary recomputations of transforms, and contributes to better interactive performance.

For example, here is a graph of the transform tree used to plot data to the graph:
The framework can be used for both affine and non-affine transformations. However, for speed, we want use the backend renderers to perform affine transformations whenever possible. Therefore, it is possible to perform just the affine or non-affine part of a transformation on a set of data. The affine is always assumed to occur after the non-affine. For any transform:

\[
\text{full transform} = \text{non-affine part} + \text{affine part}
\]

The backends are not expected to handle non-affine transformations themselves.
class `matplotlib.transforms.TransformNode`(*shorthand_name=None*)

Bases: `object`

`TransformNode` is the base class for anything that participates in the transform tree and needs to invalidate its parents or be invalidated. This includes classes that are not really transforms, such as bounding boxes, since some transforms depend on bounding boxes to compute their values.

Creates a new `TransformNode`.

**shorthand_name - a string representing the “name” of this** transform. The name carries no significance other than to improve the readability of `str(transform)` when `DEBUG=True`.

**frozen()**

Returns a frozen copy of this transform node. The frozen copy will not update when its children change. Useful for storing a previously known state of a transform where `copy.deepcopy()` might normally be used.

**invalidate()**

Invalidates this `TransformNode` and triggers an invalidation of its ancestors. Should be called any time the transform changes.

**pass_through = False**

If `pass_through` is `True`, all ancestors will always be invalidated, even if `’self’` is already invalid.

**set_children(*children*)**

Set the children of the transform, to let the invalidation system know which transforms can invalidate this transform. Should be called from the constructor of any transforms that depend on other transforms.

---

class `matplotlib.transforms.BboxBase`(*shorthand_name=None*)

Bases: `matplotlib.transforms.TransformNode`

This is the base class of all bounding boxes, and provides read-only access to its data. A mutable bounding box is provided by the `Bbox` class.

The canonical representation is as two points, with no restrictions on their ordering. Convenience properties are provided to get the left, bottom, right and top edges and width and height, but these are not stored explicitly.

Creates a new `TransformNode`.

**shorthand_name - a string representing the “name” of this** transform. The name carries no significance other than to improve the readability of `str(transform)` when `DEBUG=True`.

**anchored(c, container=None)**

Return a copy of the `Bbox`, shifted to position `c` within a container.

`c`: may be either:

- a sequence `(cx, cy)` where `cx` and `cy` range from 0 to 1, where 0 is left or bottom and 1 is right or top
- a string: - ‘C’ for centered - ‘S’ for bottom-center - ‘SE’ for bottom-left - ‘E’ for left - etc.

Optional argument `container` is the box within which the `Bbox` is positioned; it defaults to the initial `Bbox`. 
bounds
    (property) Returns \((x_0, y_0, \text{width}, \text{height})\).

contains\((x, y)\)
    Returns \text{True} if \((x, y)\) is a coordinate inside the bounding box or on its edge.

containsx\((x)\)
    Returns \text{True} if \(x\) is between or equal to \(x_0\) and \(x_1\).

containsy\((y)\)
    Returns \text{True} if \(y\) is between or equal to \(y_0\) and \(y_1\).

corners()
    Return an array of points which are the four corners of this rectangle. For example, if this \text{Bbox}
is defined by the points \((a, b)\) and \((c, d)\), \text{corners()} returns \((a, b), (a, d), (c, b)\) and \((c, d)\).

count_contains\((\text{vertices})\)
    Count the number of vertices contained in the \text{Bbox}.

    \text{vertices} is a Nx2 Numpy array.

count_overlaps\((\text{bboxes})\)
    Count the number of bounding boxes that overlap this one.

    \text{bboxes} is a sequence of \text{BboxBase} objects

expanded\((sw, sh)\)
    Return a new \text{Bbox} which is this \text{Bbox} expanded around its center by the given factors \(sw\) and \(sh\).

extents
    (property) Returns \((x_0, y_0, x_1, y_1)\).

frozen()
    \text{TransformNode} is the base class for anything that participates in the transform tree and needs to
invalidate its parents or be invalidated. This includes classes that are not really transforms, such as bounding boxes, since some transforms depend on bounding boxes to compute their values.

fully_contains\((x, y)\)
    Returns \text{True} if \((x, y)\) is a coordinate inside the bounding box, but not on its edge.

fully_containsx\((x)\)
    Returns \text{True} if \(x\) is between but not equal to \(x_0\) and \(x_1\).

fully_containsy\((y)\)
    Returns \text{True} if \(y\) is between but not equal to \(y_0\) and \(y_1\).

fully_overlaps\((\text{other})\)
    Returns \text{True} if this bounding box overlaps with the given bounding box \text{other}, but not on its edge alone.

height
    (property) The height of the bounding box. It may be negative if \(y_1 < y_0\).
static intersection(bbox1, bbox2)
   Return the intersection of the two bboxes or None if they do not intersect.
   Implements the algorithm described at:
   http://www.tekpool.com/node/2687

intervalx
   (property) intervalx is the pair of x coordinates that define the bounding box. It is not guar-
   anteed to be sorted from left to right.

intervaly
   (property) intervaly is the pair of y coordinates that define the bounding box. It is not guar-
   anteed to be sorted from bottom to top.

inverse_transformed(transform)
   Return a new Bbox object, statically transformed by the inverse of the given transform.

is_unit()
   Returns True if the Bbox is the unit bounding box from (0, 0) to (1, 1).

max
   (property) max is the top-right corner of the bounding box.

min
   (property) min is the bottom-left corner of the bounding box.

overlaps(other)
   Returns True if this bounding box overlaps with the given bounding box other.

p0
   (property) p0 is the first pair of (x, y) coordinates that define the bounding box. It is not guaran-
   teed to be the bottom-left corner. For that, use min.

p1
   (property) p1 is the second pair of (x, y) coordinates that define the bounding box. It is not
   guaranteed to be the top-right corner. For that, use max.

padded(p)
   Return a new Bbox that is padded on all four sides by the given value.

rotated(radians)
   Return a new bounding box that bounds a rotated version of this bounding box by the given
   radians. The new bounding box is still aligned with the axes, of course.

shrunk(mx, my)
   Return a copy of the Bbox, shrunk by the factor mx in the x direction and the factor my in the y
   direction. The lower left corner of the box remains unchanged. Normally mx and my will be
   less than 1, but this is not enforced.

shrunk_to_aspect(box_aspect, container=None, fig_aspect=1.0)
   Return a copy of the Bbox, shrunk so that it is as large as it can be while having the desired
   aspect ratio, box_aspect. If the box coordinates are relative—that is, fractions of a larger box
   such as a figure—then the physical aspect ratio of that figure is specified with fig_aspect, so that
   box_aspect can also be given as a ratio of the absolute dimensions, not the relative dimensions.
size
   (property) The width and height of the bounding box. May be negative, in the same way as width and height.

splitx(*args)
e.g., bbox.splitx(f1, f2, ...)
   Returns a list of new Bbox objects formed by splitting the original one with vertical lines at fractional positions f1, f2, ...

splity(*args)
e.g., bbox.splity(f1, f2, ...)
   Returns a list of new Bbox objects formed by splitting the original one with horizontal lines at fractional positions f1, f2, ...

transformed(transform)
   Return a new Bbox object, statically transformed by the given transform.

translated(tx, ty)
   Return a copy of the Bbox, statically translated by tx and ty.

static union(bboxes)
   Return a Bbox that contains all of the given bboxes.

width
   (property) The width of the bounding box. It may be negative if x1 < x0.

x0
   (property) x0 is the first of the pair of x coordinates that define the bounding box. x0 is not guaranteed to be less than x1. If you require that, use xmin.

x1
   (property) x1 is the second of the pair of x coordinates that define the bounding box. x1 is not guaranteed to be greater than x0. If you require that, use xmax.

xmax
   (property) xmax is the right edge of the bounding box.

xmin
   (property) xmin is the left edge of the bounding box.

y0
   (property) y0 is the first of the pair of y coordinates that define the bounding box. y0 is not guaranteed to be less than y1. If you require that, use ymin.

y1
   (property) y1 is the second of the pair of y coordinates that define the bounding box. y1 is not guaranteed to be greater than y0. If you require that, use ymax.

ymax
   (property) ymax is the top edge of the bounding box.

ymin
   (property) ymin is the bottom edge of the bounding box.
class matplotlib.transforms.Bbox(points, **kwargs)
Bases: matplotlib.transforms.BboxBase

A mutable bounding box.

points: a 2x2 numpy array of the form [[x0, y0], [x1, y1]]

If you need to create a Bbox object from another form of data, consider the static methods unit(), from_bounds() and from_extents().

static from_bounds(x0, y0, width, height)
  (staticmethod) Create a new Bbox from x0, y0, width and height.
  width and height may be negative.

static from_extents(*args)
  (staticmethod) Create a new Bbox from left, bottom, right and top.
  The y-axis increases upwards.

get_points()
  Get the points of the bounding box directly as a numpy array of the form: [[x0, y0], [x1, y1]].

ignore(value)
  Set whether the existing bounds of the box should be ignored by subsequent calls to
  update_from_data_xy().

  value:
  • When True, subsequent calls to update_from_data_xy() will ignore the existing bounds
    of the Bbox.
  • When False, subsequent calls to update_from_data_xy() will include the existing
    bounds of the Bbox.

mutated()
  return whether the bbox has changed since init

mutatedx()
  return whether the x-limits have changed since init

mutatedy()
  return whether the y-limits have changed since init

static null()
  (staticmethod) Create a new null Bbox from (inf, inf) to (-inf, -inf).

set(other)
  Set this bounding box from the “frozen” bounds of another Bbox.

set_points(points)
  Set the points of the bounding box directly from a numpy array of the form: [[x0, y0], [x1, y1]].
  No error checking is performed, as this method is mainly for internal use.

static unit()
  (staticmethod) Create a new unit Bbox from (0, 0) to (1, 1).
**update_from_data**(x, y, ignore=None)

Deprecated since version 2.0: The update_from_data function was deprecated in version 2.0. Use update_from_data xy instead.

Update the bounds of the **Bbox** based on the passed in data. After updating, the bounds will have positive **width** and **height**; x0 and y0 will be the minimal values.

- **x**: a numpy array of x-values
- **y**: a numpy array of y-values
- **ignore**:
  - when True, ignore the existing bounds of the **Bbox**.
  - when False, include the existing bounds of the **Bbox**.
  - when None, use the last value passed to **ignore()**.

**update_from_data_xy**(xy, ignore=None, updatex=True, updatey=True)

Update the bounds of the **Bbox** based on the passed in data. After updating, the bounds will have positive **width** and **height**; x0 and y0 will be the minimal values.

- **xy**: a numpy array of 2D points
- **ignore**:
  - when True, ignore the existing bounds of the **Bbox**.
  - when False, include the existing bounds of the **Bbox**.
  - when None, use the last value passed to **ignore()**.
- **updatex**: when True, update the x values
- **updatey**: when True, update the y values

**update_from_path**(path, ignore=None, updatex=True, updatey=True)

Update the bounds of the **Bbox** based on the passed in data. After updating, the bounds will have positive **width** and **height**; x0 and y0 will be the minimal values.

- **path**: a **Path** instance
- **ignore**:
  - when True, ignore the existing bounds of the **Bbox**.
  - when False, include the existing bounds of the **Bbox**.
  - when None, use the last value passed to **ignore()**.
- **updatex**: when True, update the x values
- **updatey**: when True, update the y values

**class** matplotlib.transforms.TransformedBbox(bbox, transform, **kwargs)

**Bases**: matplotlib.transforms.BboxBase

A **Bbox** that is automatically transformed by a given transform. When either the child bounding box or transform changes, the bounds of this bbox will update accordingly.
bbox: a child Bbox

transform: a 2D Transform

get_points()

Get the points of the bounding box directly as a numpy array of the form: [[x0, y0], [x1, y1]].

class matplotlib.transforms.Transform(shorthand_name=None)

Bases: matplotlib.transforms.TransformNode

The base class of all TransformNode instances that actually perform a transformation.

All non-affine transformations should be subclasses of this class. New affine transformations should be subclasses of Affine2D.

Subclasses of this class should override the following members (at minimum):

- input_dims
- output_dims
- transform()
- is_separable
- has_inverse
- inverted() (if has_inverse is True)

If the transform needs to do something non-standard with matplotlib.path.Path objects, such as adding curves where there were once line segments, it should override:

- transform_path()

Creates a new TransformNode.

shorthand_name - a string representing the “name” of this transform. The name carries no significance other than to improve the readability of str(transform) when DEBUG=True.

contains_branch(other)

Return whether the given transform is a sub-tree of this transform.

This routine uses transform equality to identify sub-trees, therefore in many situations it is object id which will be used.

For the case where the given transform represents the whole of this transform, returns True.

contains_branch_seperately(other_transform)

Returns whether the given branch is a sub-tree of this transform on each separate dimension.

A common use for this method is to identify if a transform is a blended transform containing an axes’ data transform. e.g.:

```python
x_isdata, y_isdata = trans.contains_branch_seperately(ax.transData)
```

depth

Returns the number of transforms which have been chained together to form this Transform instance.
Note: For the special case of a Composite transform, the maximum depth of the two is returned.

get_affine()
Get the affine part of this transform.

get_matrix()
Get the Affine transformation array for the affine part of this transform.

has_inverse = False
True if this transform has a corresponding inverse transform.

input_dims = None
The number of input dimensions of this transform. Must be overridden (with integers) in the subclass.

inverted()
Return the corresponding inverse transformation.

The return value of this method should be treated as temporary. An update to self does not cause a corresponding update to its inverted copy.

    x === self.inverted().transform(self.transform(x))

is_separable = False
True if this transform is separable in the x- and y- dimensions.

output_dims = None
The number of output dimensions of this transform. Must be overridden (with integers) in the subclass.

transform(values)
Performs the transformation on the given array of values.

Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape (N x output_dims).

Alternatively, accepts a numpy array of length input_dims and returns a numpy array of length output_dims.

transform_affine(values)
Performs only the affine part of this transformation on the given array of values.

transform(values) is always equivalent to transform_affine(transform_non_affine(values)).

In non-affine transformations, this is generally a no-op. In affine transformations, this is equivalent to transform(values).

Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape (N x output_dims).

Alternatively, accepts a numpy array of length input_dims and returns a numpy array of length output_dims.

transform_angles(angles, pts, radians=False, pushoff=1e-05)
Performs transformation on a set of angles anchored at specific locations.
The *angles* must be a column vector (i.e., numpy array).

The *pts* must be a two-column numpy array of x,y positions (angle transforms currently only work in 2D). This array must have the same number of rows as *angles*.

*radians* indicates whether or not input angles are given in radians (True) or degrees (False; the default).

*pushoff* is the distance to move away from *pts* for determining transformed angles (see discussion of method below).

The transformed angles are returned in an array with the same size as *angles*.

The generic version of this method uses a very generic algorithm that transforms *pts*, as well as locations very close to *pts*, to find the angle in the transformed system.

**transform_bbox** (*bbox*)

Transform the given bounding box.

Note, for smarter transforms including caching (a common requirement for matplotlib figures), see *TransformedBbox*.

**transform_non_affine** (*values*)

Performs only the non-affine part of the transformation.

transform(*values*) is always equivalent to transform_affine(transform_non_affine(*values*)).

In non-affine transformations, this is generally equivalent to transform(*values*). In affine transformations, this is always a no-op.

Accepts a numpy array of shape (N x *input_dims*) and returns a numpy array of shape (N x *output_dims*).

Alternatively, accepts a numpy array of length *input_dims* and returns a numpy array of length *output_dims*.

**transform_path** (*path*)

Returns a transformed path.

*path*: a *Path* instance.

In some cases, this transform may insert curves into the path that began as line segments.

**transform_path_affine** (*path*)

Returns a path, transformed only by the affine part of this transform.

*path*: a *Path* instance.

transform_path(*path*) is equivalent to transform_path_affine(transform_path_non_affine(*values*)).

**transform_path_non_affine** (*path*)

Returns a path, transformed only by the non-affine part of this transform.

*path*: a *Path* instance.

transform_path(*path*) is equivalent to transform_path_affine(transform_path_non_affine(*values*)).
transform_point(point)
A convenience function that returns the transformed copy of a single point.

The point is given as a sequence of length input_dims. The transformed point is returned as a
sequence of length output_dims.

class matplotlib.transforms.TransformWrapper(child)
Bases: matplotlib.transforms.Transform

A helper class that holds a single child transform and acts equivalently to it.

This is useful if a node of the transform tree must be replaced at run time with a transform of a different
type. This class allows that replacement to correctly trigger invalidation.

Note that TransformWrapper instances must have the same input and output dimensions during their
entire lifetime, so the child transform may only be replaced with another child transform of the same
dimensions.

child: A class:Transform instance. This child may later be replaced with set().

frozen()
Returns a frozen copy of this transform node. The frozen copy will not update when its children
change. Useful for storing a previously known state of a transform where copy.deepcopy() might normally be used.

set(child)
Replace the current child of this transform with another one.

The new child must have the same number of input and output dimensions as the current child.

class matplotlib.transforms.AffineBase(*args, **kwargs)
Bases: matplotlib.transforms.Transform

The base class of all affine transformations of any number of dimensions.

get_affine()
Get the affine part of this transform.

transform(values)
Performs the transformation on the given array of values.

Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape (N x
output_dims).

Alternatively, accepts a numpy array of length input_dims and returns a numpy array of length
output_dims.

transform_affine(values)
Performs only the affine part of this transformation on the given array of values.

transform(values) is always equivalent to transform_affine(transform_non_affine(values)).

In non-affine transformations, this is generally a no-op. In affine transformations, this is equivalent
to transform(values).

Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape (N x
output_dims).
Alternatively, accepts a numpy array of length `input_dims` and returns a numpy array of length `output_dims`.

**transform_non_affine(points)**
Performs only the non-affine part of the transformation.

```
transform(values) is always equivalent to transform_affine(transform_non_affine(values)).
```

In non-affine transformations, this is generally equivalent to `transform(values)`. In affine transformations, this is always a no-op.

Accepts a numpy array of shape `(N x input_dims)` and returns a numpy array of shape `(N x output_dims)`.

Alternatively, accepts a numpy array of length `input_dims` and returns a numpy array of length `output_dims`.

**transform_path(path)**
Returns a transformed path.

```
path: a Path instance.
```

In some cases, this transform may insert curves into the path that began as line segments.

**transform_path_affine(path)**
Returns a path, transformed only by the affine part of this transform.

```
path: a Path instance.
```

**transform_path_non_affine(path)**
Returns a path, transformed only by the non-affine part of this transform.

```
path: a Path instance.
```

```
transform_path(path) is equivalent to transform_path_affine(transform_path_non_affine(values))
```

```
transform_path_non_affine(path) is equivalent to transform_path_affine(transform_path_non_affine(values))
```

**class** matplotlib.transforms.Affine2DBase(*args, **kwargs)

```
Bases: matplotlib.transforms.AffineBase
```

The base class of all 2D affine transformations.

2D affine transformations are performed using a 3x3 numpy array:

```
a c e
b d f
0 0 1
```

This class provides the read-only interface. For a mutable 2D affine transformation, use `Affine2D`.

Subclasses of this class will generally only need to override a constructor and `get_matrix()` that generates a custom 3x3 matrix.

**frozen()**

Returns a frozen copy of this transform node. The frozen copy will not update when its children change. Useful for storing a previously known state of a transform where `copy.deepcopy()` might normally be used.
inverted()
Return the corresponding inverse transformation.

The return value of this method should be treated as temporary. An update to self does not cause a corresponding update to its inverted copy.

\[ x == self.inverted().transform(self.transform(x)) \]

static matrix_from_values(a, b, c, d, e, f)
(staticmethod) Create a new transformation matrix as a 3x3 numpy array of the form:

\[
\begin{pmatrix}
a & c & e \\
b & d & f \\
0 & 0 & 1 \\
\end{pmatrix}
\]

to_values()
Return the values of the matrix as a sequence (a,b,c,d,e,f)

transform_affine(points)
Performs only the affine part of this transformation on the given array of values.

transform(values) is always equivalent to transform_affine(transform_non_affine(values)).

In non-affine transformations, this is generally a no-op. In affine transformations, this is equivalent to transform(values).

Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape (N x output_dims).

Alternatively, accepts a numpy array of length input_dims and returns a numpy array of length output_dims.

transform_point(point)
A convenience function that returns the transformed copy of a single point.

The point is given as a sequence of length input_dims. The transformed point is returned as a sequence of length output_dims.

class matplotlib.transforms.Affine2D(matrix=None, **kwargs)
Bases: matplotlib.transforms.Affine2DBase

A mutable 2D affine transformation.

Initialize an Affine transform from a 3x3 numpy float array:

\[
\begin{pmatrix}
a & c & e \\
b & d & f \\
0 & 0 & 1 \\
\end{pmatrix}
\]

If matrix is None, initialize with the identity transform.

clear()
Reset the underlying matrix to the identity transform.

static from_values(a, b, c, d, e, f)
(staticmethod) Create a new Affine2D instance from the given values:
get_matrix()
Get the underlying transformation matrix as a 3x3 numpy array:

\[
\begin{pmatrix}
a & c & e \\
b & d & f \\
0 & 0 & 1
\end{pmatrix}
\]

static identity()
(staticmethod) Return a new Affine2D object that is the identity transform.
Unless this transform will be mutated later on, consider using the faster IdentityTransform class instead.

rotate(theta)
Add a rotation (in radians) to this transform in place.

Returns self, so this method can easily be chained with more calls to rotate(), rotate_deg(), translate() and scale().

rotate_around(x, y, theta)
Add a rotation (in radians) around the point (x, y) in place.

Returns self, so this method can easily be chained with more calls to rotate(), rotate_deg(), translate() and scale().

rotate_deg(degrees)
Add a rotation (in degrees) to this transform in place.

Returns self, so this method can easily be chained with more calls to rotate(), rotate_deg(), translate() and scale().

rotate_deg_around(x, y, degrees)
Add a rotation (in degrees) around the point (x, y) in place.

Returns self, so this method can easily be chained with more calls to rotate(), rotate_deg(), translate() and scale().

scale(sx, sy=None)
Adds a scale in place.

If sy is None, the same scale is applied in both the x- and y-directions.

Returns self, so this method can easily be chained with more calls to rotate(), rotate_deg(), translate() and scale().

set(other)
Set this transformation from the frozen copy of another Affine2DBase object.
**set_matrix**(*mtx*)

Set the underlying transformation matrix from a 3x3 numpy array:

```
\[
\begin{bmatrix}
    a & c & e \\
    b & d & f \\
    0 & 0 & 1
\end{bmatrix}
\]
```

**skew**(*xShear*, *yShear*)

Adds a skew in place.

*xShear* and *yShear* are the shear angles along the *x*- and *y*-axes, respectively, in radians.

Returns *self*, so this method can easily be chained with more calls to *rotate*, *rotate_deg*, *translate* and *scale*.

**skew_deg**(*xShear*, *yShear*)

Adds a skew in place.

*xShear* and *yShear* are the shear angles along the *x*- and *y*-axes, respectively, in degrees.

Returns *self*, so this method can easily be chained with more calls to *rotate*, *rotate_deg*, *translate* and *scale*.

**translate**(*tx*, *ty*)

Adds a translation in place.

Returns *self*, so this method can easily be chained with more calls to *rotate*, *rotate_deg*, *translate* and *scale*.

class matplotlib.transforms.IdentityTransform(*args*, **kwargs)

Bases: matplotlib.transforms.Affine2DBase

A special class that does one thing, the identity transform, in a fast way.

**frozen()**

Returns a frozen copy of this transform node. The frozen copy will not update when its children change. Useful for storing a previously known state of a transform where copy.deepcopy() might normally be used.

**get_affine()**

Return the corresponding inverse transformation.

The return value of this method should be treated as temporary. An update to *self* does not cause a corresponding update to its inverted copy.

```
x == self.inverted().transform(self.transform(x))
```

**get_matrix()**

Get the Affine transformation array for the affine part of this transform.

**inverted()**

Return the corresponding inverse transformation.

The return value of this method should be treated as temporary. An update to *self* does not cause a corresponding update to its inverted copy.
x === self.inverted().transform(self.transform(x))

**transform(points)**

Performs only the non-affine part of the transformation.

transform(values) is always equivalent to transform_affine(transform_non_affine(values)).

In non-affine transformations, this is generally equivalent to transform(values). In affine transformations, this is always a no-op.

Accepts a numpy array of shape \((N \times \text{input_dims})\) and returns a numpy array of shape \((N \times \text{output_dims})\).

Alternatively, accepts a numpy array of length \(\text{input_dims}\) and returns a numpy array of length \(\text{output_dims}\).

**transform_affine(points)**

Performs only the non-affine part of the transformation.

transform(values) is always equivalent to transform_affine(transform_non_affine(values)).

In non-affine transformations, this is generally equivalent to transform(values). In affine transformations, this is always a no-op.

Accepts a numpy array of shape \((N \times \text{input_dims})\) and returns a numpy array of shape \((N \times \text{output_dims})\).

Alternatively, accepts a numpy array of length \(\text{input_dims}\) and returns a numpy array of length \(\text{output_dims}\).

**transform_non_affine(points)**

Performs only the non-affine part of the transformation.

transform(values) is always equivalent to transform_affine(transform_non_affine(values)).

In non-affine transformations, this is generally equivalent to transform(values). In affine transformations, this is always a no-op.

Accepts a numpy array of shape \((N \times \text{input_dims})\) and returns a numpy array of shape \((N \times \text{output_dims})\).

Alternatively, accepts a numpy array of length \(\text{input_dims}\) and returns a numpy array of length \(\text{output_dims}\).

**transform_path(path)**

Returns a path, transformed only by the non-affine part of this transform.

* path: a Path instance.

transform_path(path) is equivalent to transform_path_affine(transform_path_non_affine(values)).

**transform_path_affine(path)**

Returns a path, transformed only by the non-affine part of this transform.

* path: a Path instance.

transform_path(path) is equivalent to transform_path_affine(transform_path_non_affine(values)).
transform_path_non_affine(path)

Returns a path, transformed only by the non-affine part of this transform.

path: a Path instance.

transform_path(path) is equivalent to transform_path_affine(transform_path_non_affine(values)).

class matplotlib.transforms.BlendedGenericTransform(x_transform, y_transform, **kwargs)

Bases: matplotlib.transforms.Transform

A “blended” transform uses one transform for the x-direction, and another transform for the y-direction.

This “generic” version can handle any given child transform in the x- and y-directions.

Create a new “blended” transform using x_transform to transform the x-axis and y_transform to transform the y-axis.

You will generally not call this constructor directly but use the blended_transform_factory() function instead, which can determine automatically which kind of blended transform to create.

frozen()

Returns a frozen copy of this transform node. The frozen copy will not update when its children change. Useful for storing a previously known state of a transform where copy.deepcopy() might normally be used.

get_affine()

Get the affine part of this transform.

inverted()

Return the corresponding inverse transformation.

The return value of this method should be treated as temporary. An update to self does not cause a corresponding update to its inverted copy.

x == self.inverted().transform(self.transform(x))

transform_non_affine(points)

Performs only the non-affine part of the transformation.

transform(values) is always equivalent to transform_affine(transform_non_affine(values)).

In non-affine transformations, this is generally equivalent to transform(values). In affine transformations, this is always a no-op.

Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape (N x output_dims).

Alternatively, accepts a numpy array of length input_dims and returns a numpy array of length output_dims.

class matplotlib.transforms.BlendedAffine2D(x_transform, y_transform, **kwargs)

Bases: matplotlib.transforms.Affine2DBase

A “blended” transform uses one transform for the x-direction, and another transform for the y-direction.
This version is an optimization for the case where both child transforms are of type `Affine2DBase`. Create a new “blended” transform using `x_transform` to transform the x-axis and `y_transform` to transform the y-axis.

Both `x_transform` and `y_transform` must be 2D affine transforms.

You will generally not call this constructor directly but use the `blended_transform_factory()` function instead, which can determine automatically which kind of blended transform to create.

```python
get_matrix()
```

Get the Affine transformation array for the affine part of this transform.

```python
matplotlib.transforms.blended_transform_factory(x_transform, y_transform)
```

Create a new “blended” transform using `x_transform` to transform the x-axis and `y_transform` to transform the y-axis.

A faster version of the blended transform is returned for the case where both child transforms are affine.

```python
class matplotlib.transforms.CompositeGenericTransform(a, b, **kwargs)
```

A composite transform formed by applying transform `a` then transform `b`.

This “generic” version can handle any two arbitrary transformations.

Create a new composite transform that is the result of applying transform `a` then transform `b`.

You will generally not call this constructor directly but use the `composite_transform_factory()` function instead, which can automatically choose the best kind of composite transform instance to create.

```python
frozen()
```

Returns a frozen copy of this transform node. The frozen copy will not update when its children change. Useful for storing a previously known state of a transform where `copy.deepcopy()` might normally be used.

```python
get_affine()
```

Get the affine part of this transform.

```python
inverted()
```

Return the corresponding inverse transformation.

The return value of this method should be treated as temporary. An update to `self` does not cause a corresponding update to its inverted copy.

```python
x == self.inverted().transform(self.transform(x))
```

```python
transform_affine(points)
```

Performs only the affine part of this transformation on the given array of values.

`transform(values)` is always equivalent to `transform_affine(transform_non_affine(values))`.

In non-affine transformations, this is generally a no-op. In affine transformations, this is equivalent to `transform(values)`. 
Accepts a numpy array of shape \((N \times \text{input dims})\) and returns a numpy array of shape \((N \times \text{output dims})\).

Alternatively, accepts a numpy array of length \(\text{input dims}\) and returns a numpy array of length \(\text{output dims}\).

**transform_non_affine**\((\text{points})\)

Performs only the non-affine part of the transformation.

**transform(values)** is always equivalent to **transform_affine(transform_non_affine(values))**.

In non-affine transformations, this is generally equivalent to **transform(values)**. In affine transformations, this is always a no-op.

Accepts a numpy array of shape \((N \times \text{input dims})\) and returns a numpy array of shape \((N \times \text{output dims})\).

Alternatively, accepts a numpy array of length \(\text{input dims}\) and returns a numpy array of length \(\text{output dims}\).

**transform_path_non_affine**\((\text{path})\)

Returns a path, transformed only by the non-affine part of this transform.

\(\text{path: a Path instance.}\)

**transform_path(path)** is equivalent to **transform_path_affine(transform_path_non_affine(values))**.

class matplotlib.transforms.CompositeAffine2D\((a, b, **\text{kwargs})\)

Bases: matplotlib.transforms.Affine2DBase

A composite transform formed by applying transform \(a\) then transform \(b\).

This version is an optimization that handles the case where both \(a\) and \(b\) are 2D affines.

Create a new composite transform that is the result of applying transform \(a\) then transform \(b\).

Both \(a\) and \(b\) must be instances of Affine2DBase.

You will generally not call this constructor directly but use the composite_transform_factory() function instead, which can automatically choose the best kind of composite transform instance to create.

**get_matrix()**

Get the Affine transformation array for the affine part of this transform.

class matplotlib.transforms.composite_transform_factory\((a, b)\)

Create a new composite transform that is the result of applying transform \(a\) then transform \(b\).

Shortcut versions of the blended transform are provided for the case where both child transforms are affine, or one or the other is the identity transform.

Composite transforms may also be created using the ‘+’ operator, e.g.:

```python
\[c = a + b\]
```

class matplotlib.transforms.BboxTransform\((\text{boxin}, \text{boxout}, **\text{kwargs})\)

Bases: matplotlib.transforms.Affine2DBase
BboxTransform linearly transforms points from one Bbox to another Bbox.

Create a new BboxTransform that linearly transforms points from boxin to boxout.

get_matrix()
Get the Affine transformation array for the affine part of this transform.

class matplotlib.transforms.BboxTransformTo(boxout, **kwargs)
BboxTransformTo is a transformation that linearly transforms points from the unit bounding box to a given Bbox.

Create a new BboxTransformTo that linearly transforms points from the unit bounding box to boxout.

get_matrix()
Get the Affine transformation array for the affine part of this transform.

class matplotlib.transforms.BboxTransformFrom(boxin, **kwargs)
BboxTransformFrom linearly transforms points from a given Bbox to the unit bounding box.

get_matrix()
Get the Affine transformation array for the affine part of this transform.

class matplotlib.transforms.ScaledTranslation(xt, yt, scale_trans, **kwargs)
A transformation that translates by xt and yt, after xt and yt have been transformad by the given transform scale_trans.

get_matrix()
Get the Affine transformation array for the affine part of this transform.

class matplotlib.transforms.TransformedPath(path, transform)
A TransformedPath caches a non-affine transformed copy of the Path. This cached copy is automatically updated when the non-affine part of the transform changes.

Note: Paths are considered immutable by this class. Any update to the path’s vertices/codes will not trigger a transform recomputation.

Create a new TransformedPath from the given Path and Transform.

get_fully_transformed_path()
Return a fully-transformed copy of the child path.

get_transformed_path_and_affine()
Return a copy of the child path, with the non-affine part of the transform already applied, along with the affine part of the path necessary to complete the transformation.
get_transformed_points_and_affine()

Return a copy of the child path, with the non-affine part of the transform already applied, along with the affine part of the path necessary to complete the transformation. Unlike get_transformed_path_and_affine(), no interpolation will be performed.

matplotlib.transforms.nonsingular(vmin, vmax, expander=0.001, tiny=1e-15, increasing=True)

Modify the endpoints of a range as needed to avoid singularities.

vmin, vmax the initial endpoints.

tiny threshold for the ratio of the interval to the maximum absolute value of its endpoints. If the interval is smaller than this, it will be expanded. This value should be around 1e-15 or larger; otherwise the interval will be approaching the double precision resolution limit.

expander fractional amount by which vmin and vmax are expanded if the original interval is too small, based on tiny.

increasing: [True | False] If True (default), swap vmin, vmax if vmin > vmax

Returns vmin, vmax, expanded and/or swapped if necessary.

If either input is inf or NaN, or if both inputs are 0 or very close to zero, it returns -expander, expander.
54.1 matplotlib.tri

Unstructured triangular grid functions.

```python
class matplotlib.tri.Triangulation(x, y, triangles=None, mask=None)
```

An unstructured triangular grid consisting of `npoints` points and `ntri` triangles. The triangles can either be specified by the user or automatically generated using a Delaunay triangulation.

**Parameters**

- `x`, `y`: array_like of shape `(npoints)`
  - Coordinates of grid points.
- `triangles`: integer array_like of shape `(ntri, 3)`, optional
  - For each triangle, the indices of the three points that make up the triangle, ordered in an anticlockwise manner. If not specified, the Delaunay triangulation is calculated.
- `mask`: boolean array_like of shape `(ntri)`, optional
  - Which triangles are masked out.

**Notes**

For a Triangulation to be valid it must not have duplicate points, triangles formed from colinear points, or overlapping triangles.

**Attributes**

- `edges`
- `neighbors`
- `is_delaunay` (bool) Whether the Triangulation is a calculated Delaunay triangulation (where `triangles` was not specified) or not.

**calculate_plane_coefficients(z)**

Calculate plane equation coefficients for all unmasked triangles from the point `(x,y)` coordinates and specified `z`-array of shape `(npoints)`. Returned array has shape `(npoints,3)` and allows
z-value at (x,y) position in triangle tri to be calculated using \( z = \text{array}[\text{tri},0] \cdot x + \text{array}[\text{tri},1] \cdot y + \text{array}[\text{tri},2]. \)

**edges**

Return integer array of shape (nedges,2) containing all edges of non-masked triangles.

Each edge is the start point index and end point index. Each edge (start,end and end,start) appears only once.

**static get_from_args_and_kwars**(*args, **kwargs)*

Return a Triangulation object from the args and kwars, and the remaining args and kwars with the consumed values removed.

There are two alternatives: either the first argument is a Triangulation object, in which case it is returned, or the args and kwars are sufficient to create a new Triangulation to return. In the latter case, see Triangulation.__init__ for the possible args and kwars.

**get_masked_triangles**()

Return an array of triangles that are not masked.

**get_trifinder**()

Return the default matplotlib.tri.TriFinder of this triangulation, creating it if necessary. This allows the same TriFinder object to be easily shared.

**neighbors**

Return integer array of shape (ntri,3) containing neighbor triangles.

For each triangle, the indices of the three triangles that share the same edges, or -1 if there is no such neighboring triangle. neighbors[i,j] is the triangle that is the neighbor to the edge from point index triangles[i,j] to point index triangles[i,(j+1)%3].

**set_mask**(mask)

Set or clear the mask array. This is either None, or a boolean array of shape (ntri).

**class matplotlib.tri.TriFinder**(triangulation)

Abstract base class for classes used to find the triangles of a Triangulation in which (x,y) points lie.

Rather than instantiate an object of a class derived from TriFinder, it is usually better to use the function matplotlib.tri.Triangulation.get_trifinder().

Derived classes implement __call__(x,y) where x,y are array_like point coordinates of the same shape.

**class matplotlib.tri.TrapezoidMapTriFinder**(triangulation)

Bases: matplotlib.tri.trifinder.TriFinder

The triangulation must be valid, i.e. it must not have duplicate points, triangles formed from colinear points, or overlapping triangles. The algorithm has some tolerance to triangles formed from colinear points, but this should not be relied upon.

__call__(x, y)

Return an array containing the indices of the triangles in which the specified x,y points lie, or -1 for points that do not lie within a triangle.
$x, y$ are array_like $x$ and $y$ coordinates of the same shape and any number of dimensions.

Returns integer array with the same shape and $x$ and $y$.

class matplotlib.tri.TriInterpolator(triangulation, z, trifinder=None)

Abstract base class for classes used to perform interpolation on triangular grids.

Derived classes implement the following methods:

- __call__(x, y), where $x, y$ are array_like point coordinates of the same shape, and that returns a masked array of the same shape containing the interpolated $z$-values.

- gradient(x, y), where $x, y$ are array_like point coordinates of the same shape, and that returns a list of 2 masked arrays of the same shape containing the 2 derivatives of the interpolator (derivatives of interpolated $z$ values with respect to $x$ and $y$).

class matplotlib.tri.LinearTriInterpolator(triangulation, z, trifinder=None)

Bases: matplotlib.tri.TriInterpolator

A LinearTriInterpolator performs linear interpolation on a triangular grid.

Each triangle is represented by a plane so that an interpolated value at point $(x,y)$ lies on the plane of the triangle containing $(x,y)$. Interpolated values are therefore continuous across the triangulation, but their first derivatives are discontinuous at edges between triangles.

Parameters triangulation : Triangulation object

The triangulation to interpolate over.

$z$ : array_like of shape (npoints,)

Array of values, defined at grid points, to interpolate between.

trifinder : TriFinder object, optional

If this is not specified, the Triangulation’s default TriFinder will be used by calling matplotlib.tri.Triangulation.get_trifinder().

Methods

__call__(x, y)  (Returns interpolated values at x,y points)

gradient(x, y)  (Returns interpolated derivatives at x,y points)

__call__(x, y)

Returns a masked array containing interpolated values at the specified x,y points.

Parameters x, y : array-like

$x$ and $y$ coordinates of the same shape and any number of dimensions.

Returns z : np.ma.array

Masked array of the same shape as $x$ and $y$ : values corresponding to $(x, y)$ points outside of the triangulation are masked out.

gradient(x, y)

Returns a list of 2 masked arrays containing interpolated derivatives at the specified x,y points.
Parameters \( x, y \) : array-like

\( x \) and \( y \) coordinates of the same shape and any number of dimensions.

Returns \( dzdx, dzdy \) : np.ma.array

2 masked arrays of the same shape as \( x \) and \( y \); values corresponding to \((x,y)\) points outside of the triangulation are masked out. The first returned array contains the values of \( \frac{\partial z}{\partial x} \) and the second those of \( \frac{\partial z}{\partial y} \).

class matplotlib.tri.CubicTriInterpolator(
    triangulation, 
    z, 
    kind='min_E', 
    trifinder=None,
    dz=None)

Bases: matplotlib.tri.triinterpolate.TriInterpolator

A CubicTriInterpolator performs cubic interpolation on triangular grids.

In one-dimension - on a segment - a cubic interpolating function is defined by the values of the function and its derivative at both ends. This is almost the same in 2-d inside a triangle, except that the values of the function and its 2 derivatives have to be defined at each triangle node.

The CubicTriInterpolator takes the value of the function at each node - provided by the user - and internally computes the value of the derivatives, resulting in a smooth interpolation. (As a special feature, the user can also impose the value of the derivatives at each node, but this is not supposed to be the common usage.)

Parameters triangulation : Triangulation object

The triangulation to interpolate over.

\( z \) : array_like of shape (npoints,)

Array of values, defined at grid points, to interpolate between.

kind : \{‘min_E’, ‘geom’, ‘user’\}, optional

Choice of the smoothing algorithm, in order to compute the interpolant derivatives (defaults to ‘min_E’):

- if ‘min_E’: (default) The derivatives at each node is computed to minimize a bending energy.
- if ‘geom’: The derivatives at each node is computed as a weighted average of relevant triangle normals. To be used for speed optimization (large grids).
- if ‘user’: The user provides the argument \( dz \), no computation is hence needed.

trifinder : TriFinder object, optional

If not specified, the Triangulation’s default TriFinder will be used by calling matplotlib.tri.Triangulation.get_trifinder().

dz : tuple of array_likes (dzdx, dzdy), optional

Used only if kind = ‘user’. In this case \( dz \) must be provided as (dzdx, dzdy) where dzdx, dzdy are arrays of the same shape as \( z \) and are the interpolant first derivatives at the triangulation points.
Notes

This note is a bit technical and details the way a CubicTriInterpolator computes a cubic interpolation.

The interpolation is based on a Clough-Tocher subdivision scheme of the triangulation mesh (to make it clearer, each triangle of the grid will be divided in 3 child-triangles, and on each child triangle the interpolated function is a cubic polynomial of the 2 coordinates). This technique originates from FEM (Finite Element Method) analysis; the element used is a reduced Hsieh-Clough-Tocher (HCT) element. Its shape functions are described in [R1]. The assembled function is guaranteed to be C1-smooth, i.e. it is continuous and its first derivatives are also continuous (this is easy to show inside the triangles but is also true when crossing the edges).

In the default case (kind = ’min_E’), the interpolant minimizes a curvature energy on the functional space generated by the HCT element shape functions - with imposed values but arbitrary derivatives at each node. The minimized functional is the integral of the so-called total curvature (implementation based on an algorithm from [R2] - PCG sparse solver):

\[
E(z) = \frac{1}{2} \int_\Omega \left( \left( \frac{\partial^2 z}{\partial x^2} \right)^2 + \left( \frac{\partial^2 z}{\partial y^2} \right)^2 + 2 \left( \frac{\partial^2 z}{\partial y \partial x} \right)^2 \right) \, dx \, dy
\]  
(54.1)

If the case kind = ’geom’ is chosen by the user, a simple geometric approximation is used (weighted average of the triangle normal vectors), which could improve speed on very large grids.

References

[R1], [R2]

Methods

__call__(x, y)  
(Returns interpolated values at x,y points)

gradient(x, y)  
(Returns interpolated derivatives at x,y points)

__call__(x, y)

Returns a masked array containing interpolated values at the specified x,y points.

Parameters x, y : array-like

x and y coordinates of the same shape and any number of dimensions.

Returns z : np.ma.array

Masked array of the same shape as x and y; values corresponding to (x, y) points outside of the triangulation are masked out.

gradient(x, y)

Returns a list of 2 masked arrays containing interpolated derivatives at the specified x,y points.

Parameters x, y : array-like
x and y coordinates of the same shape and any number of dimensions.

**Returns** dzdx, dzdy : np.ma.array

2 masked arrays of the same shape as x and y; values corresponding to (x,y) points outside of the triangulation are masked out. The first returned array contains the values of $\frac{\partial z}{\partial x}$ and the second those of $\frac{\partial z}{\partial y}$.

**Examples**

An example of effective application is shown below (plot of the direction of the vector field derivated from a known potential field):

**class** matplotlib.tri.TriRefiner(triangulation)

Abstract base class for classes implementing mesh refinement.

A TriRefiner encapsulates a Triangulation object and provides tools for mesh refinement and interpolation.

Derived classes must implements:

- `refine_triangulation(return_tri_index=False, **kwargs)` , where the optional keyword arguments `kwargs` are defined in each TriRefiner concrete implementation, and which returns :
- a refined triangulation
- optionally (depending on return_tri_index), for each point of the refined triangulation: the index of the initial triangulation triangle to which it belongs.

**refine_field(z, triinterpolator=None, **kwargs)**, where:
- z array of field values (to refine) defined at the base triangulation nodes
- triinterpolator is a TriInterpolator (optional)
- the other optional keyword arguments kwargs are defined in each TriRefiner concrete implementation

and which returns (as a tuple) a refined triangular mesh and the interpolated values of the field at the refined triangulation nodes.

class matplotlib.tri.UniformTriRefiner(triangulation)

Bases: matplotlib.tri.trirefine.TriRefiner

Uniform mesh refinement by recursive subdivisions.

**Parameters**

**triangulation : Triangulation**

The encapsulated triangulation (to be refined)

**refine_field(z, triinterpolator=None, subdiv=3)**

Refines a field defined on the encapsulated triangulation.

Returns refi_tri (refined triangulation), refi_z (interpolated values of the field at the node of the refined triangulation).

**Parameters**

**z :** 1d-array-like of length n_points

Values of the field to refine, defined at the nodes of the encapsulated triangulation. (n_points is the number of points in the initial triangulation)

**triinterpolator :** TriInterpolator, optional

Interpolator used for field interpolation. If not specified, a CubicTriInterpolator will be used.

**subdiv :** integer, optional

Recursion level for the subdivision. Defaults to 3. Each triangle will be divided into 4**subdiv child triangles.

**Returns**

**refi_tri :** Triangulation object

The returned refined triangulation

**refi_z :** 1d array of length: refi_tri node count.

The returned interpolated field (at refi_tri nodes)
Examples

The main application of this method is to plot high-quality iso-contours on a coarse triangular grid (e.g., triangulation built from relatively sparse test data):

```
refine_triangulation(return_tri_index=False, subdiv=3)
```

Computes an uniformly refined triangulation `refi_triangulation` of the encapsulated triangulation.

This function refines the encapsulated triangulation by splitting each father triangle into 4 child sub-triangles built on the edges midside nodes, recursively (level of recursion `subdiv`). In the end, each triangle is hence divided into $4^{**\text{subdiv}}$ child triangles. The default value for `subdiv` is 3 resulting in 64 refined subtriangles for each triangle of the initial triangulation.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return_tri_index</td>
<td>boolean, optional&lt;br&gt;Boolean indicating whether an index table indicating the father triangle index of each point will be returned. Default value False.</td>
</tr>
<tr>
<td>subdiv</td>
<td>integer, optional&lt;br&gt;Recursion level for the subdivision. Defaults value 3. Each triangle will be divided into $4^{**\text{subdiv}}$ child triangles.</td>
</tr>
</tbody>
</table>

**Returns**

`refi_triangulation` : `Triangulation`

The returned refined triangulation
**found_index** : array-like of integers

Index of the initial triangulation containing triangle, for each point of `refi_triangulation`. Returned only if `return_tri_index` is set to True.

class matplotlib.tri.TriAnalyzer(triangulation)

Define basic tools for triangular mesh analysis and improvement.

A TriAnalyzer encapsulates a `Triangulation` object and provides basic tools for mesh analysis and mesh improvement.

**Parameters**

**triangulation** : `Triangulation` object

The encapsulated triangulation to analyze.

**Attributes**

`scale_factors`

`circle_ratios(rescale=True)`

Returns a measure of the triangulation triangles flatness.

The ratio of the incircle radius over the circumcircle radius is a widely used indicator of a triangle flatness. It is always $\leq 0.5$ and $= 0.5$ only for equilateral triangles. Circle ratios below 0.01 denote very flat triangles.

To avoid unduly low values due to a difference of scale between the 2 axis, the triangular mesh can first be rescaled to fit inside a unit square with `scale_factors` (Only if `rescale` is True, which is its default value).

**Parameters**

**rescale** : boolean, optional

If True, a rescaling will be internally performed (based on `scale_factors`, so that the (unmasked) triangles fit exactly inside a unit square mesh. Default is True.

**Returns**

**circle_ratios** : masked array

Ratio of the incircle radius over the circumcircle radius, for each ‘rescaled’ triangle of the encapsulated triangulation. Values corresponding to masked triangles are masked out.

`get_flat_tri_mask(min_circle_ratio=0.01, rescale=True)`

Eliminates excessively flat border triangles from the triangulation.

Returns a mask `new_mask` which allows to clean the encapsulated triangulation from its border-located flat triangles (according to their `circle_ratios()`). This mask is meant to be subsequently applied to the triangulation using `matplotlib.tri.Triangulation.set_mask()`. `new_mask` is an extension of the initial triangulation mask in the sense that an initially masked triangle will remain masked.

The `new_mask` array is computed recursively; at each step flat triangles are removed only if they share a side with the current mesh border. Thus no new holes in the triangulated domain will be created.
Parameters `min_circle_ratio` : float, optional

Border triangles with incircle/circumcircle radii ratio \( r/R \) will be removed if \( r/R < min\_circle\_ratio \). Default value: 0.01

`rescale` : boolean, optional

If True, a rescaling will first be internally performed (based on `scale_factors`), so that the (unmasked) triangles fit exactly inside a unit square mesh. This rescaling accounts for the difference of scale which might exist between the 2 axes. Default (and recommended) value is True.

Returns `new_mask` : array-like of booleans

Mask to apply to encapsulated triangulation. All the initially masked triangles remain masked in the `new_mask`.

Notes

The rationale behind this function is that a Delaunay triangulation - of an unstructured set of points - sometimes contains almost flat triangles at its border, leading to artifacts in plots (especially for high-resolution contouring). Masked with computed `new_mask`, the encapsulated triangulation would contain no more unmasked border triangles with a circle ratio below `min_circle_ratio`, thus improving the mesh quality for subsequent plots or interpolation.

Examples

Please refer to the following illustrating example:
**scale_factors**

Factors to rescale the triangulation into a unit square.

Returns $k$, tuple of 2 scale factors.

**Returns** $k$ : tuple of 2 floats ($k_x$, $k_y$)

Tuple of floats that would rescale the triangulation: [$\text{triangulation.x} \times k_x$, $\text{triangulation.y} \times k_y$] fits exactly inside a unit square.
This module contains a class representing a Type 1 font.

This version reads pfa and pfb files and splits them for embedding in pdf files. It also supports SlantFont and ExtendFont transformations, similarly to pdfTeX and friends. There is no support yet for subsetting.

Usage:

```python
>>> font = Type1Font(filename)
>>> clear_part, encrypted_part, finale = font.parts
>>> slanted_font = font.transform({'slant': 0.167})
>>> extended_font = font.transform({'extend': 1.2})
```

Sources:

- Adobe Technical Note #5040, Supporting Downloadable PostScript Language Fonts.

```python
class matplotlib.type1font.Type1Font(input)

Bases: object

A class representing a Type-1 font, for use by backends.

parts
   A 3-tuple of the cleartext part, the encrypted part, and the finale of zeros.

prop
   A dictionary of font properties.

Initialize a Type-1 font. input can be either the file name of a pfb file or a 3-tuple of already-decoded Type-1 font parts.
```

```python
parts

prop
```
transform(effects)

Transform the font by slanting or extending. effects should be a dict where effects['slant'] is the tangent of the angle that the font is to be slanted to the right (so negative values slant to the left) and effects['extend'] is the multiplier by which the font is to be extended (so values less than 1.0 condense). Returns a new Type1Font object.

matplotlib.type1font.ord(x)
56.1 matplotlib.units

The classes here provide support for using custom classes with matplotlib, e.g., those that do not expose the array interface but know how to convert themselves to arrays. It also supports classes with units and units conversion. Use cases include converters for custom objects, e.g., list of datetime objects, as well as for objects that are unit aware. We don’t assume any particular units implementation, rather a units implementation must provide a ConversionInterface, and the register with the Registry converter dictionary. For example, here is a complete implementation which supports plotting with native datetime objects:

```python
import matplotlib.units as units
import matplotlib.dates as dates
import matplotlib.ticker as ticker
import datetime

class DateConverter(units.ConversionInterface):
    @staticmethod
    def convert(value, unit, axis):
        'convert value to a scalar or array'
        return dates.date2num(value)

    @staticmethod
    def axisinfo(unit, axis):
        'return major and minor tick locators and formatters'
        if unit!='date': return None
        majloc = dates.AutoDateLocator()
        majfmt = dates.AutoDateFormatter(majloc)
        return AxisInfo(majloc=majloc,
                        majfmt=majfmt,
                        label='date')

    @staticmethod
    def default_units(x, axis):
        'return the default unit for x or None'
        return 'date'

# finally we register our object type with a converter
units.registry[datetime.date] = DateConverter()
```
class matplotlib.units.AxisInfo(majloc=None, minloc=None, majfmt=None, minfmt=None, label=None, default_limits=None)

Bases: object

information to support default axis labeling and tick labeling, and default limits

majloc and minloc: TickLocators for the major and minor ticks majfmt and minfmt: TickFormatters for the major and minor ticks label: the default axis label default_limits: the default min, max of the axis if no data is present If any of the above are None, the axis will simply use the default

class matplotlib.units.ConversionInterface

Bases: object

The minimal interface for a converter to take custom instances (or sequences) and convert them to values mpl can use

static axisinfo(unit, axis)

return an units.AxisInfo instance for axis with the specified units

static convert(obj, unit, axis)

convert obj using unit for the specified axis. If obj is a sequence, return the converted sequence. The output must be a sequence of scalars that can be used by the numpy array layer

static default_units(x, axis)

return the default unit for x or None for the given axis

static is_numlike(x)

The matplotlib datalim, autoscaling, locators etc work with scalars which are the units converted to floats given the current unit. The converter may be passed these floats, or arrays of them, even when units are set. Derived conversion interfaces may opt to pass plain-ol unitless numbers through the conversion interface and this is a helper function for them.

class matplotlib.units.Registry

Bases: dict

register types with conversion interface

get_converter(x)

get the converter interface instance for x, or None
57.1 matplotlib.widgets

57.1.1 GUI neutral widgets

Widgets that are designed to work for any of the GUI backends. All of these widgets require you to predefine a `matplotlib.axes.Axes` instance and pass that as the first arg. `matplotlib` doesn’t try to be too smart with respect to layout – you will have to figure out how wide and tall you want your Axes to be to accommodate your widget.

```python
class matplotlib.widgets.AxesWidget(ax)
    Bases: matplotlib.widgets.Widget

    Widget that is connected to a single Axes.

    To guarantee that the widget remains responsive and not garbage-collected, a reference to the object
    should be maintained by the user.

    This is necessary because the callback registry maintains only weak-refs to the functions, which are
    member functions of the widget. If there are no references to the widget object it may be garbage
    collected which will disconnect the callbacks.

    Attributes:

    ax [Axes] The parent axes for the widget

    canvas [FigureCanvasBase subclass] The parent figure canvas for the widget.

    active [bool] If False, the widget does not respond to events.

    connect_event(event, callback)
        Connect callback with an event.

        This should be used in lieu of figure.canvas.mpl_connect since this function stores callback
        ids for later clean up.

    disconnect_events()
        Disconnect all events created by this widget.
```

```python
class matplotlib.widgets.Button(ax, label, image=None, color='0.85', hovercolor='0.95')
    Bases: matplotlib.widgets.AxesWidget
```
A GUI neutral button.

For the button to remain responsive you must keep a reference to it.

The following attributes are accessible

- **ax** The `matplotlib.axes.Axes` the button renders into.
- **label** A `matplotlib.text.Text` instance.
- **color** The color of the button when not hovering.
- **hovercolor** The color of the button when hovering.

Call `on_clicked()` to connect to the button

**Parameters**

- **ax**: `matplotlib.axes.Axes`
  - The `matplotlib.axes.Axes` instance the button will be placed into.
- **label**: `str`
  - The button text. Accepts string.
- **image**: `array, mpl image, Pillow Image`
  - The image to place in the button, if not `None`. Can be any legal arg to `imshow`
    (numpy array, matplotlib Image instance, or Pillow Image).
- **color**: `color`
  - The color of the button when not activated
- **hovercolor**: `color`
  - The color of the button when the mouse is over it

**disconnect**(cid)

remove the observer with connection id `cid`

**on_clicked**(func)

When the button is clicked, call this `func` with event.

A connection id is returned. It can be used to disconnect the button from its callback.

**class** `matplotlib.widgets.CheckButtons(ax, labels, actives)`

**Bases**: `matplotlib.widgets.AxesWidget`

A GUI neutral radio button.

For the check buttons to remain responsive you must keep a reference to this object.

The following attributes are exposed

- **ax** The `matplotlib.axes.Axes` instance the buttons are located in
- **labels** List of `matplotlib.text.Text` instances
- **lines** List of `(line1, line2)` tuples for the x’s in the check boxes. These lines exist for each
  box, but have `set_visible(False)` when its box is not checked.
- **rectangles** List of `matplotlib.patches.Rectangle` instances
Connect to the CheckButtons with the `on_clicked()` method

Add check buttons to `matplotlib.axes.Axes` instance `ax`

`labels` A len(buttons) list of labels as strings

`actives`

A len(buttons) list of booleans indicating whether the button is active

`disconnect(cid)`
remove the observer with connection id `cid`

`on_clicked(func)`
When the button is clicked, call `func` with button label
A connection id is returned which can be used to disconnect

`set_active(index)`
Directly (de)activate a check button by index.

`index` is an index into the original label list that this object was constructed with. Raises ValueError if `index` is invalid.

Callbacks will be triggered if `eventson` is True.

```python
class matplotlib.widgets.Cursor(ax, horizOn=True, vertOn=True, useblit=False, **lineprops)
```

Bases: `matplotlib.widgets.AxesWidget`

A horizontal and vertical line that spans the axes and moves with the pointer. You can turn off the hline or vline respectively with the following attributes:

- `horizOn` Controls the visibility of the horizontal line
- `vertOn` Controls the visibility of the horizontal line

and the visibility of the cursor itself with the `visible` attribute.

For the cursor to remain responsive you must keep a reference to it.

Add a cursor to `ax`. If `useblit=True`, use the backend-dependent blitting features for faster updates (GTKAgg only for now). `lineprops` is a dictionary of line properties.
clear(event)
clear the cursor

onmove(event)
on mouse motion draw the cursor if visible

class matplotlib.widgets.EllipseSelector(ax, onselect, drawtype='box', minspanx=None, minspany=None, useblit=False, lineprops=None, rectprops=None, spancoords='data', button=None, maxdist=10, marker_props=None, interactive=False, state_modifier_keys=None)

Bases: matplotlib.widgets.RectangleSelector

Select an elliptical region of an axes.

For the cursor to remain responsive you must keep a reference to it.

Example usage:

```python
from matplotlib.widgets import EllipseSelector
from pylab import *

def onselect(eclick, erelease):
    'eclick and erelease are matplotlib events at press and release'
    print('startposition : (%f, %f)' % (eclick.xdata, eclick.ydata))
```

1662 Chapter 57. widgets
print(' endposition : (%f, %f)' % (erelease.xdata, erelease.ydata))
print(' used button : ', eclick.button)

def toggle_selector(event):
    print(' Key pressed. ')
    if event.key in ['Q', 'q'] and toggle_selector.ES.active:
        print(' EllipseSelector deactivated. ')
        toggle_selector.RS.set_active(False)
    if event.key in ['A', 'a'] and not toggle_selector.ES.active:
        print(' EllipseSelector activated. ')
        toggle_selector.ES.set_active(True)

x = arange(100)/(99.0)
y = sin(x)
fig = figure
ax = subplot(111)
ax.plot(x, y)
toggle_selector.ES = EllipseSelector(ax, onselect, drawtype='line')
connect('key_press_event', toggle_selector)
show()

Create a selector in ax. When a selection is made, clear the span and call onselect with:

```python
onselect(pos_1, pos_2)
```

and clear the drawn box/line. The pos_1 and pos_2 are arrays of length 2 containing the x- and y-coordinate.

If minspanx is not None then events smaller than minspanx in x direction are ignored (it’s the same for y).

The rectangle is drawn with rectprops; default:

```python
rectprops = dict(facecolor='red', edgecolor='black',
                  alpha=0.2, fill=True)
```

The line is drawn with lineprops; default:

```python
lineprops = dict(color='black', linestyle='-',
                  linewidth=2, alpha=0.5)
```

Use drawtype if you want the mouse to draw a line, a box or nothing between click and actual position by setting drawtype = 'line', drawtype='box' or drawtype = 'none'.

spancoords is one of ‘data’ or ‘pixels’. If ‘data’, minspanx and minspanx will be interpreted in the same coordinates as the x and y axis. If ‘pixels’, they are in pixels.

button is a list of integers indicating which mouse buttons should be used for rectangle selection. You can also specify a single integer if only a single button is desired. Default is None, which does not limit which button can be used.
**Note, typically:** 1 = left mouse button 2 = center mouse button (scroll wheel) 3 = right mouse button

*interactive* will draw a set of handles and allow you interact with the widget after it is drawn.

*state_modifier_keys* are keyboard modifiers that affect the behavior of the widget.

The defaults are: `dict(move=' ', clear='escape', square='shift', center='ctrl')`

Keyboard modifiers, which: ‘move’: Move the existing shape. ‘clear’: Clear the current shape. ‘square’: Makes the shape square. ‘center’: Make the initial point the center of the shape. ‘square’ and ‘center’ can be combined.

```python
draw_shape(extents)
```

class `matplotlib.widgets.Lasso`(ax, xy, callback=None, useblit=True)

Bases: `matplotlib.widgets.AxesWidget`

Selection curve of an arbitrary shape.

The selected path can be used in conjunction with `contains_point()` to select data points from an image.

Unlike `LassoSelector`, this must be initialized with a starting point `xy`, and the `Lasso` events are destroyed upon release.

Parameters:

- **ax** [Axes] The parent axes for the widget.
- **xy** [array] Coordinates of the start of the lasso.
- **callback** [function] Whenever the lasso is released, the callback function is called and passed the vertices of the selected path.

```python
onmove(event)
```

```python
onrelease(event)
```

class `matplotlib.widgets.LassoSelector`(ax, onselect=None, useblit=True, lineprops=None, button=None)

Bases: `matplotlib.widgets._SelectorWidget`

Selection curve of an arbitrary shape.

For the selector to remain responsive you must keep a reference to it.

The selected path can be used in conjunction with `contains_point()` to select data points from an image.

In contrast to `Lasso`, `LassoSelector` is written with an interface similar to `RectangleSelector` and `SpanSelector` and will continue to interact with the axes until disconnected.

Parameters:

- **ax** [Axes] The parent axes for the widget.
**onselect** [function] Whenever the lasso is released, the onselect function is called and passed the vertices of the selected path.

Example usage:

```python
ax = subplot(111)
an.plot(x,y)

def onselect(verts):
    print(verts)
lasso = LassoSelector(ax, onselect)
```

*button* is a list of integers indicating which mouse buttons should be used for rectangle selection. You can also specify a single integer if only a single button is desired. Default is "None", which does not limit which button can be used.

Note, typically:
- 1 = left mouse button
- 2 = center mouse button (scroll wheel)
- 3 = right mouse button

**onpress**(event)

**onrelease**(event)

**class** matplotlib.widgets.LockDraw

Bases: object

Some widgets, like the cursor, draw onto the canvas, and this is not desirable under all circumstances, like when the toolbar is in zoom-to-rect mode and drawing a rectangle. The module level “lock” allows someone to grab the lock and prevent other widgets from drawing. Use `matplotlib.widgets.lock(someobj)` to prevent other widgets from drawing while you’re interacting with the canvas.

**available**(o)

drawing is available to o

**isowner**(o)

Return True if o owns this lock

**locked**

Return True if the lock is currently held by an owner

**release**(o)

release the lock

**class** matplotlib.widgets.MultiCursor(canvas, axes, useblit=True, horizOn=False, vertOn=True, **lineprops)

Bases: matplotlib.widgets.Widget

Provide a vertical (default) and/or horizontal line cursor shared between multiple axes.

For the cursor to remain responsive you must keep a reference to it.
Example usage:

```python
from matplotlib.widgets import MultiCursor
from pylab import figure, show, np

t = np.arange(0.0, 2.0, 0.01)
s1 = np.sin(2*np.pi*t)
s2 = np.sin(4*np.pi*t)
fig = figure()
ax1 = fig.add_subplot(211)
ax1.plot(t, s1)
ax2 = fig.add_subplot(212, sharex=ax1)
ax2.plot(t, s2)
multi = MultiCursor(fig.canvas, (ax1, ax2), color='r', lw=1, horizOn=False, vertOn=True)
show()

clear(event)
    clear the cursor

connect()
    connect events

disconnect()
    disconnect events

onmove(event)
```

**class** `matplotlib.widgets.RadioButtons(ax, labels, active=0, activecolor='blue')`

Bases: `matplotlib.widgets.AxesWidget`

A GUI neutral radio button.

For the buttons to remain responsive you must keep a reference to this object.

The following attributes are exposed:

- `ax` The `matplotlib.axes.Axes` instance the buttons are in
- `activecolor` The color of the button when clicked
- `labels` A list of `matplotlib.text.Text` instances
- `circles` A list of `matplotlib.patches.Circle` instances
- `value_selected` A string listing the current value selected

Connect to the RadioButtons with the `on_clicked()` method

Add radio buttons to `matplotlib.axes.Axes` instance `ax`

- `labels` A len(buttons) list of labels as strings
- `active` The index into labels for the button that is active
activecolor The color of the button when clicked

disconnect(cid)
remove the observer with connection id cid

on_clicked(func)
When the button is clicked, call func with button label

A connection id is returned which can be used to disconnect

set_active(index)
Trigger which radio button to make active.

index is an index into the original label list that this object was constructed with. Raise Value Error if the index is invalid.

Callbacks will be triggered if eventson is True.

class matplotlib.widgets.RectangleSelector(ax, onselect, drawtype='box', minspanx=None, minspany=None, useblit=False, lineprops=None, rectprops=None, spancoords='data', button=None, maxdist=10, marker_props=None, interactive=False, state_modifier_keys=None)
Bases: matplotlib.widgets._SelectorWidget
Select a rectangular region of an axes.
For the cursor to remain responsive you must keep a reference to it.

Example usage:

```python
from matplotlib.widgets import RectangleSelector
from pylab import *

def onselect(eclick, erelease):
    'eclick and erelease are matplotlib events at press and release'
    print('startposition : (%f, %f)' % (eclick.xdata, eclick.ydata))
    print('endposition : (%f, %f)' % (erelease.xdata, erelease.ydata))
    print('used button : %d, eclick.button

def toggle_selector(event):
    print('Key pressed."
    if event.key in ['Q', 'q'] and toggle_selector.RS.active:
        print('RectangleSelector deactivated.')
        toggle_selector.RS.set_active(False)
    if event.key in ['A', 'a'] and not toggle_selector.RS.active:
        print('RectangleSelector activated.')
        toggle_selector.RS.set_active(True)

x = arange(100)/(99.0)
y = sin(x)
fig = figure
ax = subplot(111)
x.plot(x,y)
```
toggle_selector.RS = RectangleSelector(ax, onselect, drawtype='line')
connect('key_press_event', toggle_selector)
show()

Create a selector in ax. When a selection is made, clear the span and call onselect with:

onselect(pos_1, pos_2)

and clear the drawn box/line. The pos_1 and pos_2 are arrays of length 2 containing the x- and y-coordinate.

If minspanx is not None then events smaller than minspanx in x direction are ignored (it’s the same for y).

The rectangle is drawn with rectprops; default:

rectprops = dict(facecolor='red', edgcolor = 'black',
                  alpha=0.2, fill=True)

The line is drawn with lineprops; default:

lineprops = dict(color='black', linestyle='-',
                  linewidth = 2, alpha=0.5)

Use drawtype if you want the mouse to draw a line, a box or nothing between click and actual position by setting

drawtype = 'line', drawtype='box' or drawtype = 'none'.

spancoords is one of ‘data’ or ‘pixels’. If ‘data’, minspanx and minspanx will be interpreted in the same coordinates as the x and y axis. If ‘pixels’, they are in pixels.

button is a list of integers indicating which mouse buttons should be used for rectangle selection. You can also specify a single integer if only a single button is desired. Default is None, which does not limit which button can be used.

Note, typically: 1 = left mouse button 2 = center mouse button (scroll wheel) 3 = right mouse button

interactive will draw a set of handles and allow you interact with the widget after it is drawn.

state_modifier_keys are keyboard modifiers that affect the behavior of the widget.

The defaults are: dict(move=‘’, clear=’escape’, square=’shift’, center=’ctrl’)

Keyboard modifiers, which: ‘move’: Move the existing shape. ‘clear’: Clear the current shape. ‘square’: Makes the shape square. ‘center’: Make the initial point the center of the shape. ‘square’ and ‘center’ can be combined.

center
   Center of rectangle

corners
   Corners of rectangle from lower left, moving clockwise.
**draw_shape**(*extents*)

**edge_centers**
Midpoint of rectangle edges from left, moving clockwise.

**extents**
Return (xmin, xmax, ymin, ymax).

**geometry**

```python
class matplotlib.widgets.Slider(ax, label, valmin, valmax, valinit=0.5, valfmt='%.2f', closedmin=True, closedmax=True, slidermin=None, slidermax=None, dragging=True, **kwargs)
```

Bases: *matplotlib.widgets.AxesWidget*

A slider representing a floating point range.

For the slider to remain responsive you must maintain a reference to it.

**The following attributes are defined**

- **ax**: the slider *matplotlib.axes.Axes* instance
  - **val**: the current slider value
  - **vline** [a *matplotlib.lines.Line2D* instance] representing the initial value of the slider
  - **poly** [A *matplotlib.patches.Polygon* instance] which is the slider knob
  - **valfmt**: the format string for formatting the slider text
  - **label** [a *matplotlib.text.Text* instance] for the slider label
  - **closedmin**: whether the slider is closed on the minimum
  - **closedmax**: whether the slider is closed on the maximum
  - **slidermin** [another slider - if not *None*, this slider must be] greater than **slidermin**
  - **slidermax** [another slider - if not *None*, this slider must be] less than **slidermax**
  - **dragging**: allow for mouse dragging on slider

Call **on_changed()** to connect to the slider event

Create a slider from **valmin** to **valmax** in axes **ax**.

Additional kwargs are passed on to **self.poly** which is the *matplotlib.patches.Rectangle* that draws the slider knob. See the *matplotlib.patches.Rectangle* documentation for valid property names (e.g., *facecolor, edgecolor, alpha, ...*).

**Parameters**

- **ax**: Axes
  - The Axes to put the slider in
  - **label**: str
    - Slider label
  - **valmin**: float
```
The minimum value of the slider
valmax : float
The maximum value of the slider
valinit : float
The slider initial position
label : str
The slider label
valfmt : str
Used to format the slider value, fprint format string
closedmin : bool
Indicate whether the slider interval is closed on the bottom
closedmax : bool
Indicate whether the slider interval is closed on the top
slidermin : Slider or None
Do not allow the current slider to have a value less than slidermin
slidermax : Slider or None
Do not allow the current slider to have a value greater than slidermax
dragging : bool
if the slider can be dragged by the mouse
disconnect(cid)
remove the observer with connection id cid
on_changed(func)
When the slider value is changed, call func with the new slider position
A connection id is returned which can be used to disconnect
reset()
reset the slider to the initial value if needed
set_val(val)

class matplotlib.widgets.SpanSelector(ax, onselect, direction, minspan=None, useblit=False, rectprops=None, onmove_callback=None, span_stays=False, button=None)
Bases: matplotlib.widgets._SelectorWidget
Visually select a min/max range on a single axis and call a function with those values.
To guarantee that the selector remains responsive, keep a reference to it.
In order to turn off the SpanSelector, set `span_selector.active=False`. To turn it back on, set `span_selector.active=True`.

**Parameters**

- **ax**: `matplotlib.axes.Axes` object
- **onselect**: func(min, max), min/max are floats
- **direction**: “horizontal” or “vertical”
  - The axis along which to draw the span selector
- **minspan**: float, default is None
  - If selection is less than `minspan`, do not call `onselect`
- **useblit**: bool, default is False
  - If True, use the backend-dependent blitting features for faster canvas updates. Only available for GTKAgg right now.
- **rectprops**: dict, default is None
  - Dictionary of `matplotlib.patches.Patch` properties
- **onmove_callback**: func(min, max), min/max are floats, default is None
  - Called on mouse move while the span is being selected
- **span_stays**: bool, default is False
  - If True, the span stays visible after the mouse is released
- **button**: int or list of ints
  - Determines which mouse buttons activate the span selector
    - 1 = left mouse button
    - 2 = center mouse button (scroll wheel)
    - 3 = right mouse button

**Examples**

```python
>>> import matplotlib.pyplot as plt
>>> import matplotlib.widgets as mwidgets

>>> fig, ax = plt.subplots()
>>> ax.plot([1, 2, 3], [10, 50, 100])
>>> def onselect(vmin, vmax):
...     print(vmin, vmax)
...
>>> rectprops = dict(facecolor='blue', alpha=0.5)

>>> span = mwidgets.SpanSelector(ax, onselect, 'horizontal',
...                                rectprops=rectprops)

>>> fig.show()
```

See also: widgets example code: `span_selector.py`
ignore(event)
    return True if event should be ignored

def new_axes(ax)
    Set SpanSelector to operate on a new Axes

class matplotlib.widgets.SubplotTool(targetfig, toolfig)
    Bases: matplotlib.widgets.Widget
    A tool to adjust the subplot params of a matplotlib.figure.Figure.

    targetfig  The figure instance to adjust.

    toolfig  The figure instance to embed the subplot tool into. If None, a default figure will be created. If you are using this from the GUI

    funcbottom(val)

    funchandle(val)

    funcleft(val)

    funcright(val)

    functop(val)

    funcwspace(val)

class matplotlib.widgets.ToolHandles(ax, x, y, marker='o', marker_props=None, useblit=True)
    Bases: object
    Control handles for canvas tools.

    Parameters:
    ax : matplotlib.axes.Axes
        Matplotlib axes where tool handles are displayed.

    x, y : 1D arrays
        Coordinates of control handles.

    marker : str
        Shape of marker used to display handle. See matplotlib.pyplot.plot.

    marker_props : dict
        Additional marker properties. See matplotlib.lines.Line2D.

    closest(x, y)
        Return index and pixel distance to closest index.
set_animated(val)

set_data(pts, y=None)
    Set x and y positions of handles

set_visible(val)

x

y

class matplotlib.widgets.Widget
    Bases: object
    Abstract base class for GUI neutral widgets

    active
        Is the widget active?

drawn = True

eventson = True

get_active()
    Get whether the widget is active.

ignore(event)
    Return True if event should be ignored.

    This method (or a version of it) should be called at the beginning of any event callback.

set_active(active)
    Set whether the widget is active.
Part III

The Matplotlib FAQ
58.1 Report a compilation problem

See Getting help.
58.2 matplotlib compiled fine, but nothing shows up when I use it

The first thing to try is a clean install and see if that helps. If not, the best way to test your install is by running a script, rather than working interactively from a python shell or an integrated development environment such as IDLE which add additional complexities. Open up a UNIX shell or a DOS command prompt and cd into a directory containing a minimal example in a file. Something like simple_plot.py for example:

```python
import matplotlib.pyplot as plt
fig, ax = plt.subplots()
ax.plot([1,2,3])
plt.show()
```

and run it with:

```
python simple_plot.py --verbose-helpful
```

This will give you additional information about which backends matplotlib is loading, version information, and more. At this point you might want to make sure you understand matplotlib’s configuration process, governed by the matplotlibrc configuration file which contains instructions within and the concept of the matplotlib backend.

If you are still having trouble, see Getting help.

58.3 How to completely remove matplotlib

Occasionally, problems with matplotlib can be solved with a clean installation of the package.

The process for removing an installation of matplotlib depends on how matplotlib was originally installed on your system. Follow the steps below that goes with your original installation method to cleanly remove matplotlib from your system.

58.3.1 Source install

Unfortunately:

```
python setup.py clean
```

does not properly clean the build directory, and does nothing to the install directory. To cleanly rebuild:

1. Delete the caches from your .matplotlib configuration directory.
2. Delete the build directory in the source tree.
3. Delete any matplotlib directories or eggs from your installation directory.
58.4 How to Install

58.4.1 Source install from git

Clone the main source using one of:

```
git clone git@github.com:matplotlib/matplotlib.git
```

or:

```
git clone git://github.com/matplotlib/matplotlib.git
```

and build and install as usual with:

```
> cd matplotlib
> python setup.py install
```

**Note:** If you are on debian/ubuntu, you can get all the dependencies required to build matplotlib with:

```
sudo apt-get build-dep python-matplotlib
```

If you are on Fedora/RedHat, you can get all the dependencies required to build matplotlib by first installing `yum-builddep` and then running:

```
su -c "yum-builddep python-matplotlib"
```

This does not build matplotlib, but it does get all of the build dependencies, which will make building from source easier.

If you want to be able to follow the development branch as it changes just replace the last step with (make sure you have `setuptools` installed):

```
> python setup.py develop
```

This creates links in the right places and installs the command line script to the appropriate places.

**Note:** Mac OS X users please see the *Building on OS X* guide.

Windows users please see the *Building on Windows* guide.

Then, if you want to update your matplotlib at any time, just do:

```
> git pull
```

When you run `git pull`, if the output shows that only Python files have been updated, you are all set. If C files have changed, you need to run the `python setup.py develop` command again to compile them.

There is more information on *using git* in the developer docs.
58.5 Linux Notes

Because most Linux distributions use some sort of package manager, we do not provide a pre-built binary for the Linux platform. Instead, we recommend that you use the “Add Software” method for your system to install matplotlib. This will guarantee that everything that is needed for matplotlib will be installed as well.

If, for some reason, you can not use the package manager, Linux usually comes with at least a basic build system. Follow the instructions found above for how to build and install matplotlib.

58.6 OS-X Notes

58.6.1 Which python for OS X?

Apple ships OS X with its own Python, in /usr/bin/python, and its own copy of matplotlib. Unfortunately, the way Apple currently installs its own copies of numpy, scipy and matplotlib means that these packages are difficult to upgrade (see system python packages). For that reason we strongly suggest that you install a fresh version of Python and use that as the basis for installing libraries such as numpy and matplotlib. One convenient way to install matplotlib with other useful Python software is to use one of the excellent Python scientific software collections that are now available:

- Anaconda from Continuum Analytics
- Canopy from Enthought

These collections include Python itself and a wide range of libraries; if you need a library that is not available from the collection, you can install it yourself using standard methods such as pip. Continuum and Enthought offer their own installation support for these collections; see the Anaconda and Canopy web pages for more information.

Other options for a fresh Python install are the standard installer from python.org, or installing Python using a general OSX package management system such as homebrew or macports. Power users on OSX will likely want one of homebrew or macports on their system to install open source software packages, but it is perfectly possible to use these systems with another source for your Python binary, such as Anaconda, Canopy or Python.org Python.

58.6.2 Installing OSX binary wheels

If you are using recent Python from https://www.python.org, Macports or Homebrew, then you can use the standard pip installer to install matplotlib binaries in the form of wheels.

Python.org Python

Install pip following the standard pip install instructions. For the impatient, open a new Terminal.app window and:

```
curl -O https://bootstrap.pypa.io/get-pip.py
```
Then (Python 2.7):

```
python get-pip.py
```

or (Python 3):

```
python3 get-pip.py
```

You can now install matplotlib and all its dependencies with:

```
pip install matplotlib
```

**Macports**

For Python 2.7:

```
sudo port install py27-pip
sudo pip-2.7 install matplotlib
```

For Python 3.4:

```
sudo port install py34-pip
sudo pip-3.4 install matplotlib
```

**Homebrew**

For Python 2.7:

```
pip2 install matplotlib
```

For Python 3.4:

```
pip3 install matplotlib
```

You might also want to install IPython; we recommend you install IPython with the IPython notebook option, like this:

- Python.org Python: `pip install ipython[notebook]`
- Macports: `sudo pip-2.7 install ipython[notebook]` or `sudo pip-3.4 install ipython[notebook]`
- Homebrew: `pip2 install ipython[notebook]` or `pip3 install ipython[notebook]`

**Pip problems**

If you get errors with pip trying to run a compiler like gcc or clang, then the first thing to try is to install xcode and retry the install. If that does not work, then check Getting help.
58.6.3 Installing via OSX mpkg installer package

matplotlib also has a disk image (.dmg) installer, which contains a typical Installer.app package to install matplotlib. You should use binary wheels instead of the disk image installer if you can, because:

- wheels work with Python.org Python, homebrew and macports, the disk image installer only works with Python.org Python.
- The disk image installer doesn’t check for recent versions of packages that matplotlib depends on, and unconditionally installs the versions of dependencies contained in the disk image installer. This can overwrite packages that you have already installed, which might cause problems for other packages, if you have a pre-existing Python.org setup on your computer.

If you still want to use the disk image installer, read on.

**Note:** Before installing via the disk image installer, be sure that all of the packages were compiled for the same version of python. Often, the download site for NumPy and matplotlib will display a supposed ‘current’ version of the package, but you may need to choose a different package from the full list that was built for your combination of python and OSX.

The disk image installer will have a .dmg extension, and will have a name like matplotlib-1.4.0-py2.7-macosx10.6.dmg. The name of the installer depends on the versions of python and matplotlib it was built for, and the version of OSX that the matching Python.org installer was built for. For example, if the matching Python.org Python installer was built for OSX 10.6 or greater, the dmg file will end in -macosx10.6.dmg. You need to download this disk image file, open the disk image file by double clicking, and find the new matplotlib disk image icon on your desktop. Double click on that icon to show the contents of the image. Then double-click on the .mpkg icon, which will have a name like matplotlib-1.4.0-py2.7-macosx10.6.mpkg, it will run the Installer.app, prompt you for a password if you need system-wide installation privileges, and install to a directory like /Library/Frameworks/Python.framework/Versions/2.7/lib/python2.7/site-packages (exact path depends on your Python version).

58.6.4 Checking your installation

The new version of matplotlib should now be on your Python “path”. Check this with one of these commands at the Terminal.app command line:

```python3.4 -c 'import matplotlib; print(matplotlib.__version__, matplotlib.__file__)'```

(Python 3.4). You should see something like this:

```
1.4.0 /Library/Frameworks/Python.framework/Versions/2.7/lib/python2.7/site-packages/...matplotlib/__init__.pyc
```

where 1.4.0 is the matplotlib version you just installed, and the path following depends on whether you are using Python.org Python, Homebrew or Macports. If you see another version, or you get an error like this:
Traceback (most recent call last):
  File "<string>", line 1, in <module>
ImportError: No module named matplotlib
	hen check that the Python binary is the one you expected by doing one of these commands in Terminal.app:

    which python2.7

or:

    which python3.4

If you get the result /usr/bin/python2.7, then you are getting the Python installed with OSX, which is probably not what you want. Try closing and restarting Terminal.app before running the check again. If that doesn’t fix the problem, depending on which Python you wanted to use, consider reinstalling Python.org Python, or check your homebrew or macports setup. Remember that the disk image installer only works for Python.org Python, and will not get picked up by other Pythons. If all these fail, please let us know: see Getting help.

  - Summary
59.1 General Concepts

matplotlib has an extensive codebase that can be daunting to many new users. However, most of matplotlib can be understood with a fairly simple conceptual framework and knowledge of a few important points.

Plotting requires action on a range of levels, from the most general (e.g., ‘contour this 2-D array’) to the most specific (e.g., ‘color this screen pixel red’). The purpose of a plotting package is to assist you in visualizing your data as easily as possible, with all the necessary control – that is, by using relatively high-level commands most of the time, and still have the ability to use the low-level commands when needed.

Therefore, everything in matplotlib is organized in a hierarchy. At the top of the hierarchy is the matplotlib “state-machine environment” which is provided by the matplotlib.pyplot module. At this level, simple functions are used to add plot elements (lines, images, text, etc.) to the current axes in the current figure.

**Note:** Pyplot’s state-machine environment behaves similarly to MATLAB and should be most familiar to users with MATLAB experience.

The next level down in the hierarchy is the first level of the object-oriented interface, in which pyplot is used only for a few functions such as figure creation, and the user explicitly creates and keeps track of the figure and axes objects. At this level, the user uses pyplot to create figures, and through those figures, one or more axes objects can be created. These axes objects are then used for most plotting actions.

For even more control – which is essential for things like embedding matplotlib plots in GUI applications – the pyplot level may be dropped completely, leaving a purely object-oriented approach.
59.2 Parts of a Figure

The whole figure. The figure keeps track of all the child Axes, a smattering of ‘special’ artists (titles, figure legends, etc), and the canvas. (Don’t worry too much about the canvas, it is crucial as it is the object that actually does the drawing to get you your plot, but as the user it is more-or-less invisible to you). A figure can have any number of Axes, but to be useful should have at least one.

The easiest way to create a new figure is with pyplot:
fig = plt.figure()  # an empty figure with no axes
fig, ax_lst = plt.subplots(2, 2)  # a figure with a 2x2 grid of Axes

59.2.2 Axes

This is what you think of as ‘a plot’, it is the region of the image with the data space (marked as the inner blue box). A given figure can contain many Axes, but a given Axes object can only be in one Figure. The Axes contains two (or three in the case of 3D) Axis objects (be aware of the difference between Axes and Axis) which take care of the data limits (the data limits can also be controlled via set via the set_xlim() and set_ylim() Axes methods). Each Axes has a title (set via set_title()), an x-label (set via set_xlabel()), and a y-label set via set_ylabel().

The Axes class and it’s member functions are the primary entry point to working with the OO interface.

59.2.3 Axis

These are the number-line-like objects (circled in green). They take care of setting the graph limits and generating the ticks (the marks on the axis) and ticklabels (strings labeling the ticks). The location of the ticks is determined by a Locator object and the ticklabel strings are formatted by a Formatter. The combination of the correct Locator and Formatter gives very fine control over the tick locations and labels.

59.2.4 Artist

Basically everything you can see on the figure is an artist (even the Figure, Axes, and Axis objects). This includes Text objects, Line2D objects, collection objects, Patch objects ... (you get the idea). When the figure is rendered, all of the artists are drawn to the canvas. Most Artists are tied to an Axes; such an Artist cannot be shared by multiple Axes, or moved from one to another.

59.3 Types of inputs to plotting functions

All of plotting functions expect np.array or np.ma.masked_array as input. Classes that are ‘array-like’ such as pandas data objects and np.matrix may or may not work as intended. It is best to convert these to np.array objects prior to plotting.

For example, to covert a pandas.DataFrame

```python
a = pandas.DataFrame(np.random.rand(4,5), columns = list('abcde'))
a_asndarray = a.values
```

and to covert a np.matrix

```python
b = np.matrix([[1,2],[3,4]])
b_asarray = np.asarray(b)
```
59.4 Matplotlib, pyplot and pylab: how are they related?

Matplotlib is the whole package; `matplotlib.pyplot` is a module in matplotlib; and `pylab` is a module that gets installed alongside `matplotlib`.

Pyplot provides the state-machine interface to the underlying object-oriented plotting library. The state-machine implicitly and automatically creates figures and axes to achieve the desired plot. For example:

```python
import matplotlib.pyplot as plt
import numpy as np

x = np.linspace(0, 2, 100)

plt.plot(x, x, label='linear')
plt.plot(x, x**2, label='quadratic')
plt.plot(x, x**3, label='cubic')

plt.xlabel('x label')
plt.ylabel('y label')
plt.title("Simple Plot")
plt.legend()
plt.show()
```

The first call to `plt.plot` will automatically create the necessary figure and axes to achieve the desired plot. Subsequent calls to `plt.plot` re-use the current axes and each add another line. Setting the title, legend, and axis labels also automatically use the current axes and set the title, create the legend, and label the axis respectively.

`pylab` is a convenience module that bulk imports `matplotlib.pyplot` (for plotting) and `numpy` (for mathematics and working with arrays) in a single name space. Although many examples use `pylab`, it is no longer recommended.

For non-interactive plotting it is suggested to use `pyplot` to create the figures and then the OO interface for plotting.

59.5 Coding Styles

When viewing this documentation and examples, you will find different coding styles and usage patterns. These styles are perfectly valid and have their pros and cons. Just about all of the examples can be converted into another style and achieve the same results. The only caveat is to avoid mixing the coding styles for your own code.

**Note:** Developers for matplotlib have to follow a specific style and guidelines. See *The Matplotlib Developers' Guide.*
Of the different styles, there are two that are officially supported. Therefore, these are the preferred ways to use matplotlib.

For the pyplot style, the imports at the top of your scripts will typically be:

```python
import matplotlib.pyplot as plt
import numpy as np
```

Then one calls, for example, np.arange, np.zeros, np.pi, plt.figure, plt.plot, plt.show, etc. Use the pyplot interface for creating figures, and then use the object methods for the rest:

```python
import matplotlib.pyplot as plt
import numpy as np
x = np.arange(0, 10, 0.2)
y = np.sin(x)
fig = plt.figure()
ax = fig.add_subplot(111)
ax.plot(x, y)
plt.show()
```

So, why all the extra typing instead of the MATLAB-style (which relies on global state and a flat namespace)? For very simple things like this example, the only advantage is academic: the wordier styles are more explicit, more clear as to where things come from and what is going on. For more complicated applications, this explicitness and clarity becomes increasingly valuable, and the richer and more complete object-oriented interface will likely make the program easier to write and maintain.

Typically one finds oneself making the same plots over and over again, but with different data sets, which leads to needing to write specialized functions to do the plotting. The recommended function signature is something like:

```python
def my_plotter(ax, data1, data2, param_dict):
    """
    A helper function to make a graph
    
    Parameters
    ----------
    ax : Axes
        The axes to draw to
    data1 : array
        The x data
    data2 : array
        The y data
    param_dict : dict
        Dictionary of kwargs to pass to ax.plot
    
    Returns
    -------
    out : list
        list of artists added
    """
```
out = ax.plot(data1, data2, **param_dict)
return out

which you would then use as:

```python
fig, ax = plt.subplots(1, 1)
my_plotter(ax, data1, data2, {'marker':'x'})
```

or if you wanted to have 2 sub-plots:

```python
fig, (ax1, ax2) = plt.subplots(1, 2)
my_plotter(ax1, data1, data2, {'marker':'x'})
my_plotter(ax2, data3, data4, {'marker':'o'})
```

Again, for these simple examples this style seems like overkill, however once the graphs get slightly more complex it pays off.

### 59.6 What is a backend?

A lot of documentation on the website and in the mailing lists refers to the “backend” and many new users are confused by this term. matplotlib targets many different use cases and output formats. Some people use matplotlib interactively from the python shell and have plotting windows pop up when they type commands. Some people embed matplotlib into graphical user interfaces like wxpython or pygtk to build rich applications. Others use matplotlib in batch scripts to generate postscript images from some numerical simulations, and still others in web application servers to dynamically serve up graphs.

To support all of these use cases, matplotlib can target different outputs, and each of these capabilities is called a backend; the “frontend” is the user facing code, i.e., the plotting code, whereas the “backend” does all the hard work behind-the-scenes to make the figure. There are two types of backends: user interface backends (for use in pygtk, wxpython, tkinter, qt4, or macosx; also referred to as “interactive backends”) and hardcopy backends to make image files (PNG, SVG, PDF, PS; also referred to as “non-interactive backends”).

There are four ways to configure your backend. If they conflict each other, the method mentioned last in the following list will be used, e.g. calling `use()` will override the setting in your `matplotlibrc`.

1. The backend parameter in your `matplotlibrc` file (see Customizing matplotlib):

   ```
   backend : WXAgg  # use wxpython with antigrain (agg) rendering
   ```

2. Setting the `MPLBACKEND` environment variable, either for your current shell or for a single script:

   ```
   > export MPLBACKEND="module://my_backend"
   > python simple_plot.py
   > MPLBACKEND="module://my_backend" python simple_plot.py
   ```

   Setting this environment variable will override the backend parameter in any matplotlibrc, even if there is a matplotlibrc in your current working directory. Therefore setting `MPLBACKEND` globally, e.g. in your `.bashrc` or `.profile`, is discouraged as it might lead to counter-intuitive behavior.
3. To set the backend for a single script, you can alternatively use the \texttt{-d} command line argument:

\begin{verbatim}
> python script.py -d backend
\end{verbatim}

This method is \textbf{deprecated} as the \texttt{-d} argument might conflict with scripts which parse command line arguments (see issue \#1986). You should use \texttt{MPLBACKEND} instead.

4. If your script depends on a specific backend you can use the \texttt{use()} function:

\begin{verbatim}
import matplotlib
matplotlib.use('PS')  # generate postscript output by default
\end{verbatim}

If you use the \texttt{use()} function, this must be done before importing \texttt{matplotlib.pyplot}. Calling \texttt{use()} after pyplot has been imported will have no effect. Using \texttt{use()} will require changes in your code if users want to use a different backend. Therefore, you should avoid explicitly calling \texttt{use()} unless absolutely necessary.

\textbf{Note:} Backend name specifications are not case-sensitive; e.g., ‘GTKAgg’ and ‘gtkagg’ are equivalent.

With a typical installation of matplotlib, such as from a binary installer or a linux distribution package, a good default backend will already be set, allowing both interactive work and plotting from scripts, with output to the screen and/or to a file, so at least initially you will not need to use any of the methods given above.

If, however, you want to write graphical user interfaces, or a web application server (\textit{Matplotlib in a web application server}), or need a better understanding of what is going on, read on. To make things a little more customizable for graphical user interfaces, matplotlib separates the concept of the renderer (the thing that actually does the drawing) from the canvas (the place where the drawing goes). The canonical renderer for user interfaces is \texttt{Agg} which uses the \textit{Anti-Grain Geometry C++} library to make a raster (pixel) image of the figure. All of the user interfaces except \texttt{macosx} can be used with agg rendering, e.g., \texttt{WXAgg}, \texttt{GTKAgg}, \texttt{QT4Agg}, \texttt{QT5Agg}, \texttt{TkAgg}. In addition, some of the user interfaces support other rendering engines. For example, with GTK, you can also select GDK rendering (backend \texttt{GTK} deprecated in 2.0) or Cairo rendering (backend \texttt{GTKCairo}).

For the rendering engines, one can also distinguish between \texttt{vector} or \texttt{raster} renderers. Vector graphics languages issue drawing commands like “draw a line from this point to this point” and hence are scale free, and raster backends generate a pixel representation of the line whose accuracy depends on a DPI setting.

Here is a summary of the matplotlib renderers (there is an eponymous backed for each; these are \textit{non-interactive backends}, capable of writing to a file):
Matplotlib, Release 2.0.0

<table>
<thead>
<tr>
<th>Renderer</th>
<th>Filetypes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AGG</td>
<td>png</td>
<td>raster graphics – high quality images using the Anti-Grain Geometry engine</td>
</tr>
<tr>
<td>PS</td>
<td>ps eps</td>
<td>vector graphics – Postscript output</td>
</tr>
<tr>
<td>PDF</td>
<td>pdf</td>
<td>vector graphics – Portable Document Format</td>
</tr>

<td>Cocoa rendering in OSX windows (presently lacks blocking show() behavior when matplotlib is in non-interactive mode)</td>
</tr>
</tbody>
</table>

**59.7 WX backends**

At present the release version of wxPython (also known as wxPython classic) does not support python3. A work in progress redesigned version known as wxPython-Phoenix does support python3. Matplotlib should work with both versions.

**59.8 GTK and Cairo**

Both GTK2 and GTK3 have implicit dependencies on PyCairo regardless of the specific Matplotlib backend used. Unfortunately the latest release of PyCairo for Python3 does not implement the Python wrappers needed for the GTK3Agg backend. Cairocffi can be used as a replacement which implements the correct wrapper.
59.9 How do I select PyQt4 or PySide?

You can choose either PyQt4 or PySide when using the qt4 backend by setting the appropriate value for backend.qt4 in your matplotlibrc file. The default value is PyQt4.

The setting in your matplotlibrc file can be overridden by setting the QT_API environment variable to either pyqt or pyside to use PyQt4 or PySide, respectively.

Since the default value for the bindings to be used is PyQt4, matplotlib first tries to import it, if the import fails, it tries to import PySide.

59.10 What is interactive mode?

Use of an interactive backend (see What is a backend?) permits—but does not by itself require or ensure—plotting to the screen. Whether and when plotting to the screen occurs, and whether a script or shell session continues after a plot is drawn on the screen, depends on the functions and methods that are called, and on a state variable that determines whether matplotlib is in “interactive mode”. The default Boolean value is set by the matplotlibrc file, and may be customized like any other configuration parameter (see Customizing matplotlib). It may also be set via matplotlib.interactive(), and its value may be queried via matplotlib.is_interactive(). Turning interactive mode on and off in the middle of a stream of plotting commands, whether in a script or in a shell, is rarely needed and potentially confusing, so in the following we will assume all plotting is done with interactive mode either on or off.

Note: Major changes related to interactivity, and in particular the role and behavior of show(), were made in the transition to matplotlib version 1.0, and bugs were fixed in 1.0.1. Here we describe the version 1.0.1 behavior for the primary interactive backends, with the partial exception of macosx.

Interactive mode may also be turned on via matplotlib.pyplot.ion(), and turned off via matplotlib.pyplot.ionoff().

Note: Interactive mode works with suitable backends in ipython and in the ordinary python shell, but it does not work in the IDLE IDE. If the default backend does not support interactivity, an interactive backend can be explicitly activated using any of the methods discussed in What is a backend?.

59.10.1 Interactive example

From an ordinary python prompt, or after invoking ipython with no options, try this:

```python
import matplotlib.pyplot as plt
plt.ion()
plt.plot([1.6, 2.7])
```

Assuming you are running version 1.0.1 or higher, and you have an interactive backend installed and selected by default, you should see a plot, and your terminal prompt should also be active; you can type additional
commands such as:

```python
plt.title("interactive test")
plt.xlabel("index")
```

and you will see the plot being updated after each line. This is because you are in interactive mode and you are using pyplot functions. Now try an alternative method of modifying the plot. Get a reference to the `Axes` instance, and call a method of that instance:

```python
ax = plt.gca()
ax.plot([3.1, 2.2])
```

Nothing changed, because the Axes methods do not include an automatic call to `draw_if_interactive()`; that call is added by the pyplot functions. If you are using methods, then when you want to update the plot on the screen, you need to call `draw()`: 

```python
plt.draw()
```

Now you should see the new line added to the plot.

### 59.10.2 Non-interactive example

Start a fresh session as in the previous example, but now turn interactive mode off:

```python
import matplotlib.pyplot as plt
plt.ioff()
plt.plot([1.6, 2.7])
```

Nothing happened—or at least nothing has shown up on the screen (unless you are using `macosx` backend, which is anomalous). To make the plot appear, you need to do this:

```python
plt.show()
```

Now you see the plot, but your terminal command line is unresponsive; the `show()` command blocks the input of additional commands until you manually kill the plot window.

What good is this—being forced to use a blocking function? Suppose you need a script that plots the contents of a file to the screen. You want to look at that plot, and then end the script. Without some blocking command such as `show()`, the script would flash up the plot and then end immediately, leaving nothing on the screen.

In addition, non-interactive mode delays all drawing until `show()` is called; this is more efficient than re-drawing the plot each time a line in the script adds a new feature.

Prior to version 1.0, `show()` generally could not be called more than once in a single script (although sometimes one could get away with it); for version 1.0.1 and above, this restriction is lifted, so one can write a script like this:

```python
import numpy as np
import matplotlib.pyplot as plt
plt.ioff()
```
which makes three plots, one at a time.

### 59.10.3 Summary

In interactive mode, pyplot functions automatically draw to the screen.

When plotting interactively, if using object method calls in addition to pyplot functions, then call `draw()` whenever you want to refresh the plot.

Use non-interactive mode in scripts in which you want to generate one or more figures and display them before ending or generating a new set of figures. In that case, use `show()` to display the figure(s) and to block execution until you have manually destroyed them.

    * Contribute to Matplotlib documentation
60.1 Plotting: howto

60.1.1 Plot numpy.datetime64 values

For Matplotlib to plot dates (or any scalar with units) a converter to float needs to be registered with the matplotlib.units module. The current best converters for datetime64 values are in pandas. Simply importing pandas

```
import pandas as pd
```

should be sufficient as pandas will try to install the converters on import. If that does not work, or you need to reset munits.registry you can explicitly install the pandas converters by

```
from pandas.tseries import converter as pdtc
pdtc.register()
```

If you only want to use the pandas converter for datetime64 values

```
from pandas.tseries import converter as pdtc
import matplotlib.units as munits
import numpy as np

munits.registry[np.datetime64] = pdtc.DatetimeConverter()
```

60.1.2 Find all objects in a figure of a certain type

Every Matplotlib artist (see Artist tutorial) has a method called findobj() that can be used to recursively search the artist for any artists it may contain that meet some criteria (e.g., match all Line2D instances or match some arbitrary filter function). For example, the following snippet finds every object in the figure which has a set_color property and makes the object blue:

```
def myfunc(x):
    return hasattr(x, 'set_color')
```
for o in fig.findobj(myfunc):
    o.set_color('blue')

You can also filter on class instances:

```python
import matplotlib.text as text
for o in fig.findobj(text.Text):
    o.set_fontstyle('italic')
```

### 60.1.3 How to prevent ticklabels from having an offset

The default formatter will use an offset to reduce the length of the ticklabels. To turn this feature off on a per-axis basis:

```python
ax.get_xaxis().get_major_formatter().set_useOffset(False)
```

set the rcParam `axes.formatter.useoffset`, or use a different formatter. See `ticker` for details.

### 60.1.4 Save transparent figures

The `savefig()` command has a keyword argument `transparent` which, if ‘True’, will make the figure and axes backgrounds transparent when saving, but will not affect the displayed image on the screen.

If you need finer grained control, e.g., you do not want full transparency or you want to affect the screen displayed version as well, you can set the alpha properties directly. The figure has a `Rectangle` instance called `patch` and the axes has a Rectangle instance called `patch`. You can set any property on them directly (`facecolor`, `edgecolor`, `linewidth`, `linestyle`, `alpha`). e.g.:

```python
fig = plt.figure()
fig.patch.set_alpha(0.5)
ax = fig.add_subplot(111)
ax.patch.set_alpha(0.5)
```

If you need all the figure elements to be transparent, there is currently no global alpha setting, but you can set the alpha channel on individual elements, e.g.:

```python
ax.plot(x, y, alpha=0.5)
ax.set_xlabel('volts', alpha=0.5)
```

### 60.1.5 Save multiple plots to one pdf file

Many image file formats can only have one image per file, but some formats support multi-page files. Currently only the pdf backend has support for this. To make a multi-page pdf file, first initialize the file:

```python
from matplotlib.backends.backend_pdf import PdfPages
pp = PdfPages('multipage.pdf')
```
You can give the `PdfPages` object to `savefig()`, but you have to specify the format:

```python
plt.savefig(pp, format='pdf')
```

An easier way is to call `PdfPages.savefig`:

```python
pp.savefig()
```

Finally, the multipage pdf object has to be closed:

```python
pp.close()
```

### 60.1.6 Move the edge of an axes to make room for tick labels

For subplots, you can control the default spacing on the left, right, bottom, and top as well as the horizontal and vertical spacing between multiple rows and columns using the `matplotlib.figure.Figure.subplots_adjust()` method (in pyplot it is `subplots_adjust()`). For example, to move the bottom of the subplots up to make room for some rotated x tick labels:

```python
fig = plt.figure()
fig.subplots_adjust(bottom=0.2)
ax = fig.add_subplot(111)
```

You can control the defaults for these parameters in your `matplotlibrc` file; see *Customizing matplotlib*. For example, to make the above setting permanent, you would set:

```ini
figure.subplot.bottom : 0.2  # the bottom of the subplots of the figure
```

The other parameters you can configure are, with their defaults:

- `left = 0.125` the left side of the subplots of the figure
- `right = 0.9` the right side of the subplots of the figure
- `bottom = 0.1` the bottom of the subplots of the figure
- `top = 0.9` the top of the subplots of the figure
- `wspace = 0.2` the amount of width reserved for blank space between subplots, expressed as a fraction of the average axis width
- `hspace = 0.2` the amount of height reserved for white space between subplots, expressed as a fraction of the average axis height

If you want additional control, you can create an `Axes` using the `axes()` command (or equivalently the figure `add_axes()` method), which allows you to specify the location explicitly:

```python
ax = fig.add_axes([left, bottom, width, height])
```

where all values are in fractional (0 to 1) coordinates. See *pylab_examples example code: axes_demo.py* for an example of placing axes manually.
60.1.7 Automatically make room for tick labels

Note: This is now easier to handle than ever before. Calling `tight_layout()` can fix many common layout issues. See the Tight Layout guide.

The information below is kept here in case it is useful for other purposes.

In most use cases, it is enough to simply change the subplots adjust parameters as described in Move the edge of an axes to make room for tick labels. But in some cases, you don’t know ahead of time what your tick labels will be, or how large they will be (data and labels outside your control may be being fed into your graphing application), and you may need to automatically adjust your subplot parameters based on the size of the tick labels. Any Text instance can report its extent in window coordinates (a negative x coordinate is outside the window), but there is a rub.

The RendererBase instance, which is used to calculate the text size, is not known until the figure is drawn (draw()). After the window is drawn and the text instance knows its renderer, you can call get_window_extent(). One way to solve this chicken and egg problem is to wait until the figure is drawn by connecting (mpl_connect()) to the “on_draw” signal (DrawEvent) and get the window extent there, and then do something with it, e.g., move the left of the canvas over; see Event handling and picking.

Here is an example that gets a bounding box in relative figure coordinates (0..1) of each of the labels and uses it to move the left of the subplots over so that the tick labels fit in the figure.

```python
import matplotlib.pyplot as plt
import matplotlib.transforms as mtransforms

fig = plt.figure()
ax = fig.add_subplot(111)
ax.plot(range(10))
ax.set_yticks((2,5,7))
labels = ax.set_yticklabels(('really, really, really', 'long', 'labels'))

def on_draw(event):
    bboxes = []
    for label in labels:
        bbox = label.get_window_extent()
        # the figure transform goes from relative coords->pixels and we
        # want the inverse of that
        bboxi = bbox.inverse_transformed(fig.transFigure)
        bboxes.append(bboxi)

    # this is the bbox that bounds all the bboxes, again in relative
    # figure coords
    bbox = mtransforms.Bbox.union(bboxes)
    if fig.subplotpars.left < bbox.width:
        # we need to move it over
        fig.subplots_adjust(left=1.1*bbox.width) # pad a little
        fig.canvas.draw()
    return False

fig.canvas.mpl_connect('draw_event', on_draw)
```

60.1. Plotting: howto
60.1.8 Configure the tick linewdths

In Matplotlib, the ticks are markers. All Line2D objects support a line (solid, dashed, etc) and a marker (circle, square, tick). The tick linewidth is controlled by the “markeredgewidth” property:

```python
import matplotlib.pyplot as plt
fig = plt.figure()
ax = fig.add_subplot(111)
ax.plot(range(10))
for line in ax.get_xticklines() + ax.get_yticklines():
    line.set_markersize(10)
plt.show()
```

The other properties that control the tick marker, and all markers, are markerfacecolor, markeredgewidth, markeredgewidth, markersize. For more information on configuring ticks, see Axis containers and Tick containers.
60.1.9 Align my ylabels across multiple subplots

If you have multiple subplots over one another, and the y data have different scales, you can often get ylabels that do not align vertically across the multiple subplots, which can be unattractive. By default, Matplotlib positions the x location of the ylabel so that it does not overlap any of the y ticks. You can override this default behavior by specifying the coordinates of the label. The example below shows the default behavior in the left subplots, and the manual setting in the right subplots.

```python
import numpy as np
import matplotlib.pyplot as plt

box = dict(facecolor='yellow', pad=5, alpha=0.2)

fig = plt.figure()
fig.subplots_adjust(left=0.2, wspace=0.6)

# Fixing random state for reproducibility
np.random.seed(19680801)

ax1 = fig.add_subplot(221)
ax1.plot(2000*np.random.rand(10))
ax1.set_title('ylabels not aligned')
ax1.set_ylabel('misaligned 1', bbox=box)
ax1.set_ylim(0, 2000)
ax3 = fig.add_subplot(223)
ax3.set_ylabel('misaligned 2',bbox=box)
ax3.plot(np.random.rand(10))

labelx = -0.3  # axes coords

ax2 = fig.add_subplot(222)
ax2.set_title('ylabels aligned')
ax2.plot(2000*np.random.rand(10))
ax2.set_ylabel('aligned 1', bbox=box)
ax2.yaxis.set_label_coords(labelx, 0.5)
ax2.set_ylim(0, 2000)

ax4 = fig.add_subplot(224)
ax4.plot(np.random.rand(10))
ax4.set_ylabel('aligned 2', bbox=box)
ax4.yaxis.set_label_coords(labelx, 0.5)

plt.show()
```
60.1.10 Skip dates where there is no data

When plotting time series, e.g., financial time series, one often wants to leave out days on which there is no data, e.g., weekends. By passing in dates on the x-axis, you get large horizontal gaps on periods when there is no data. The solution is to pass in some proxy x-data, e.g., evenly sampled indices, and then use a custom formatter to format these as dates. The example below shows how to use an ‘index formatter’ to achieve the desired plot:

```python
import numpy as np
import matplotlib.pyplot as plt
import matplotlib.mlab as mlab
import matplotlib.ticker as ticker

r = mlab.csv2rec('../data/aapl.csv')
r.sort()
r = r[-30:] # get the last 30 days

N = len(r)
ind = np.arange(N) # the evenly spaced plot indices

def format_date(x, pos=None):
    thisind = np.clip(int(x+0.5), 0, N-1)
    return r.date[thisind].strftime('%Y-%m-%d')
```

```
60.1.11 Control the depth of plot elements

Within an axes, the order that the various lines, markers, text, collections, etc appear is determined by the `set_zorder()` property. The default order is patches, lines, text, with collections of lines and collections of patches appearing at the same level as regular lines and patches, respectively:

```python
line, = ax.plot(x, y, zorder=10)
```

You can also use the Axes property `set_axisbelow()` to control whether the grid lines are placed above or below your other plot elements.

60.1.12 Make the aspect ratio for plots equal

The Axes property `set_aspect()` controls the aspect ratio of the axes. You can set it to be ‘auto’, ‘equal’, or some ratio which controls the ratio:

```python
ax = fig.add_subplot(111, aspect='equal')
```

60.1.13 Multiple y-axis scales

A frequent request is to have two scales for the left and right y-axis, which is possible using `twinx()` (more than two scales are not currently supported, though it is on the wish list). This works pretty well, though there are some quirks when you are trying to interactively pan and zoom, because both scales do not get the signals.

The approach uses `twinx()` (and its sister `twiny()`) to use 2 different axes, turning the axes rectangular frame off on the 2nd axes to keep it from obscuring the first, and manually setting the tick locs and labels as desired. You can use separate `matplotlib.ticker` formatters and locators as desired because the two axes are independent.
60.1.14 Generate images without having a window appear

The easiest way to do this is use a non-interactive backend (see *What is a backend?*) such as Agg (for PNGs), PDF, SVG or PS. In your figure-generating script, just call the `matplotlib.use()` directive before importing pylab or pyplot:

```python
import matplotlib
matplotlib.use('Agg')
import matplotlib.pyplot as plt
plt.plot([1,2,3])
plt.savefig('myfig')
```

See also:

*Matplotlib in a web application server* for information about running matplotlib inside of a web application.

60.1.15 Use `show()`

When you want to view your plots on your display, the user interface backend will need to start the GUI mainloop. This is what `show()` does. It tells Matplotlib to raise all of the figure windows created so far and start the mainloop. Because this mainloop is blocking by default (i.e., script execution is paused), you should only call this once per script, at the end. Script execution is resumed after the last window is closed.
Therefore, if you are using Matplotlib to generate only images and do not want a user interface window, you do not need to call `show` (see *Generate images without having a window appear* and *What is a backend?*).

**Note:** Because closing a figure window invokes the destruction of its plotting elements, you should call `savefig()` before calling `show` if you wish to save the figure as well as view it.

New in version v1.0.0: `show` now starts the GUI mainloop only if it isn’t already running. Therefore, multiple calls to `show` are now allowed.

Having `show` block further execution of the script or the python interpreter depends on whether Matplotlib is set for interactive mode or not. In non-interactive mode (the default setting), execution is paused until the last figure window is closed. In interactive mode, the execution is not paused, which allows you to create additional figures (but the script won’t finish until the last figure window is closed).

**Note:** Support for interactive/non-interactive mode depends upon the backend. Until version 1.0.0 (and subsequent fixes for 1.0.1), the behavior of the interactive mode was not consistent across backends. As of v1.0.1, only the macOSx backend differs from other backends because it does not support non-interactive mode.

Because it is expensive to draw, you typically will not want Matplotlib to redraw a figure many times in a script such as the following:

```python
plot([1,2,3])  # draw here ?
xlabel('time')  # and here ?
ylabel('volts')  # and here ?
title('a simple plot')  # and here ?
show()         # and here ?
```

However, it is possible to force Matplotlib to draw after every command, which might be what you want when working interactively at the python console (see *Using matplotlib in a python shell*), but in a script you want to defer all drawing until the call to `show`. This is especially important for complex figures that take some time to draw. `show()` is designed to tell Matplotlib that you’re all done issuing commands and you want to draw the figure now.

**Note:** `show()` should typically only be called at most once per script and it should be the last line of your script. At that point, the GUI takes control of the interpreter. If you want to force a figure draw, use `draw()` instead.

Many users are frustrated by `show` because they want it to be a blocking call that raises the figure, pauses the script until they close the figure, and then allow the script to continue running until the next figure is created and the next show is made. Something like this:

```python
# WARNING : illustrating how NOT to use show
for i in range(10):
    # make figure i
    show()
```
This is not what `show` does and unfortunately, because doing blocking calls across user interfaces can be tricky, is currently unsupported, though we have made significant progress towards supporting blocking events.

New in version v1.0.0: As noted earlier, this restriction has been relaxed to allow multiple calls to `show`. In most backends, you can now expect to be able to create new figures and raise them in a subsequent call to `show` after closing the figures from a previous call to `show`.

### 60.1.16 Interpreting box plots and violin plots

Tukey’s box plots (Robert McGill, John W. Tukey and Wayne A. Larsen: “The American Statistician” Vol. 32, No. 1, Feb., 1978, pp. 12-16) are statistical plots that provide useful information about the data distribution such as skewness. However, bar plots with error bars are still the common standard in most scientific literature, and thus, the interpretation of box plots can be challenging for the unfamiliar reader. The figure below illustrates the different visual features of a box plot.

![Box Plot Diagram](image)

- **Q1**: Quartile 1, or median of the left data subset after dividing the original data set into 2 subsets via the median (25% of the data points fall below this threshold)
- **Q3**: Quartile 3, median of the right data subset (75% of the data points fall below this threshold)
- **IQR**: Interquartile range, Q3 - Q1
- **Outliers**: Data points are considered to be outliers if value < Q1 - 1.5 x IQR or value > Q3 + 1.5 x IQR

Violin plots are closely related to box plots but add useful information such as the distribution of the sample data (density trace). Violin plots were added in Matplotlib 1.4.

### 60.2 Contributing: howto

#### 60.2.1 Request a new feature

Is there a feature you wish Matplotlib had? Then ask! The best way to get started is to email the developer mailing list for discussion. This is an open source project developed primarily in the contributors free time, so there is no guarantee that your feature will be added. The best way to get the feature you need added is to contribute it yourself.
60.2.2 Reporting a bug or submitting a patch

The development of Matplotlib is organized through github. If you would like to report a bug or submit a patch please use that interface.

To report a bug create an issue on github (this requires having a github account). Please include a Short, Self Contained, Correct (Compilable), Example demonstrating what the bug is. Including a clear, easy to test example makes it easy for the developers to evaluate the bug. Expect that the bug reports will be a conversation. If you do not want to register with github, please email bug reports to the mailing list.

The easiest way to submit patches to Matplotlib is through pull requests on github. Please see the The Matplotlib Developers’ Guide for the details.

60.2.3 Contribute to Matplotlib documentation

Matplotlib is a big library, which is used in many ways, and the documentation has only scratched the surface of everything it can do. So far, the place most people have learned all these features are through studying the examples (Search examples), which is a recommended and great way to learn, but it would be nice to have more official narrative documentation guiding people through all the dark corners. This is where you come in.

There is a good chance you know more about Matplotlib usage in some areas, the stuff you do every day, than many of the core developers who wrote most of the documentation. Just pulled your hair out compiling Matplotlib for windows? Write a FAQ or a section for the Installation page. Are you a digital signal processing wizard? Write a tutorial on the signal analysis plotting functions like xcorr(), psd() and specgram(). Do you use Matplotlib with django or other popular web application servers? Write a FAQ or tutorial and we’ll find a place for it in the User’s Guide. Bundle Matplotlib in a py2exe app? ... I think you get the idea.

Matplotlib is documented using the sphinx extensions to restructured text (ReST). sphinx is an extensible python framework for documentation projects which generates HTML and PDF, and is pretty easy to write; you can see the source for this document or any page on this site by clicking on the Show Source link at the end of the page in the sidebar.

The sphinx website is a good resource for learning sphinx, but we have put together a cheat-sheet at Developer’s tips for documenting matplotlib which shows you how to get started, and outlines the Matplotlib conventions and extensions, e.g., for including plots directly from external code in your documents.

Once your documentation contributions are working (and hopefully tested by actually building the docs) you can submit them as a patch against git. See Install git and Reporting a bug or submitting a patch. Looking for something to do? Search for TODO or look at the open issues on github.

60.3 Matplotlib in a web application server

Many users report initial problems trying to use matplotlib in web application servers, because by default Matplotlib ships configured to work with a graphical user interface which may require an X11 connection. Since many barebones application servers do not have X11 enabled, you may get errors if you don’t configure Matplotlib for use in these environments. Most importantly, you need to decide what kinds of images you want to generate (PNG, PDF, SVG) and configure the appropriate default backend. For 99% of users,
this will be the Agg backend, which uses the C++ antigrain rendering engine to make nice PNGs. The Agg backend is also configured to recognize requests to generate other output formats (PDF, PS, EPS, SVG). The easiest way to configure Matplotlib to use Agg is to call:

```python
# do this before importing pylab or pyplot
import matplotlib
matplotlib.use('Agg')
import matplotlib.pyplot as plt
```

For more on configuring your backend, see `What is a backend?`.

Alternatively, you can avoid pylab/pyplot altogether, which will give you a little more control, by calling the API directly as shown in `api example code: agg_oo.py`.

You can either generate hardcopy on the filesystem by calling savefig:

```python
# do this before importing pylab or pyplot
import matplotlib
matplotlib.use('Agg')
import matplotlib.pyplot as plt
fig = plt.figure()
ax = fig.add_subplot(111)
ax.plot([1,2,3])
fig.savefig('test.png')
```

or by saving to a file handle:

```python
import sys
fig.savefig(sys.stdout)
```

Here is an example using Pillow. First, the figure is saved to a BytesIO object which is then fed to Pillow for further processing:

```python
from io import BytesIO
from PIL import Image
imgdata = BytesIO()
fig.savefig(imgdata, format='png')
imgdata.seek(0)  # rewind the data
im = Image.open(imgdata)
```

### 60.3.1 Matplotlib with apache

TODO; see `Contribute to Matplotlib documentation`.

### 60.3.2 Matplotlib with django

TODO; see `Contribute to Matplotlib documentation`. 
60.3.3 Matplotlib with zope

TODO; see Contribute to Matplotlib documentation.

60.3.4 Clickable images for HTML

Andrew Dalke of Dalke Scientific has written a nice article on how to make html click maps with Matplotlib agg PNGs. We would also like to add this functionality to SVG. If you are interested in contributing to these efforts that would be great.

60.4 Search examples

The nearly 300 code Matplotlib Examples included with the Matplotlib source distribution are full-text searchable from the search page, but sometimes when you search, you get a lot of results from the The Matplotlib API or other documentation that you may not be interested in if you just want to find a complete, free-standing, working piece of example code. To facilitate example searches, we have tagged every code example page with the keyword codex for code example which shouldn’t appear anywhere else on this site except in the FAQ. So if you want to search for an example that uses an ellipse, search for codex ellipse.

60.5 Cite Matplotlib

If you want to refer to Matplotlib in a publication, you can use “Matplotlib: A 2D Graphics Environment” by J. D. Hunter In Computing in Science & Engineering, Vol. 9, No. 3. (2007), pp. 90-95 (see this reference page):

```biblatex
@article{Hunter:2007,
  Address = {10662 LOS VAQUEROS CIRCLE, PO BOX 3014, LOS ALAMITOS, CA 90720-1314 USA},
  Author = {Hunter, John D.},
  Date-Added = {2010-09-23 12:22:10 -0700},
  Date-Modified = {2010-09-23 12:22:10 -0700},
  Isi = {000245668100019},
  Isi-Recid = {155389429},
  Journal = {Computing In Science \& Engineering},
  Month = {May-Jun},
  Number = {3},
  Pages = {90--95},
  Publisher = {IEEE COMPUTER SOC},
  Times-Cited = {21},
  Title = {Matplotlib: A 2D graphics environment},
  Type = {Editorial Material},
  Volume = {9},
  Year = {2007},
  Abstract = {Matplotlib is a 2D graphics package used for Python for application development, interactive scripting, and publication-quality image generation across user interfaces and operating systems.},
  Bdsk-Url-1 = {http://gateway.isiknowledge.com/gateway/Gateway.cgi?GWVersion=2&SrcApp=Alerting&SrcApp=Alerting&DestApp=WOS&DestLinkType=FullRecord;_KeyUT=000245668100019}}
```
61.1 Obtaining matplotlib version

To find out your matplotlib version number, import it and print the `__version__` attribute:

```python
>>> import matplotlib
>>> matplotlib.__version__
'0.98.0'
```

61.2 matplotlib install location

You can find what directory matplotlib is installed in by importing it and printing the `__file__` attribute:

```python
>>> import matplotlib
>>> matplotlib.__file__
'/home/jdhunter/dev/lib64/python2.5/site-packages/matplotlib/__init__.pyc'
```
61.3 matplotlib configuration and cache directory locations

Each user has a matplotlib configuration directory which may contain a matplotlibrc file. To locate your matplotlib/ configuration directory, use matplotlib.get_configdir():

```python
>>> import matplotlib as mpl
>>> mpl.get_configdir()
'/home/darren/.config/matplotlib'
```

On unix-like systems, this directory is generally located in your HOME directory under the .config/ directory.

In addition, users have a cache directory. On unix-like systems, this is separate from the configuration directory by default. To locate your .cache/ directory, use matplotlib.get_cachedir():

```python
>>> import matplotlib as mpl
>>> mpl.get_cachedir()
'/home/darren/.cache/matplotlib'
```

On windows, both the config directory and the cache directory are the same and are in your Documents and Settings or Users directory by default:

```python
>>> import matplotlib
>>> mpl.get_configdir()
'C:\Documents and Settings\jdhunter\.matplotlib'
>>> mpl.get_cachedir()
'C:\Documents and Settings\jdhunter\.matplotlib'
```

If you would like to use a different configuration directory, you can do so by specifying the location in your MPLCONFIGDIR environment variable – see Setting environment variables in Linux and OS-X. Note that MPLCONFIGDIR sets the location of both the configuration directory and the cache directory.

61.4 Getting help

There are a number of good resources for getting help with matplotlib. There is a good chance your question has already been asked:

- The mailing list archive.
- Github issues.
- Stackoverflow questions tagged matplotlib.

If you are unable to find an answer to your question through search, please provide the following information in your e-mail to the mailing list:

- your operating system; (Linux/UNIX users: post the output of `uname -a`)
- matplotlib version:
Matplotlib, Release 2.0.0

```bash
python -c 'import matplotlib; print matplotlib.__version__'
```

- where you obtained matplotlib (e.g., your Linux distribution’s packages, github, PyPi, or Anaconda or Enthought Canopy).

- any customizations to your `matplotlibrc` file (see Customizing matplotlib).

- if the problem is reproducible, please try to provide a minimal, standalone Python script that demonstrates the problem. This is the critical step. If you can’t post a piece of code that we can run and reproduce your error, the chances of getting help are significantly diminished. Very often, the mere act of trying to minimize your code to the smallest bit that produces the error will help you find a bug in your code that is causing the problem.

- you can get very helpful debugging output from matplotlib by running your script with a `verbose-helpful` or `--verbose-debug` flags and posting the verbose output the lists:

  ```bash
  > python simple_plot.py --verbose-helpful > output.txt
  ```

If you compiled matplotlib yourself, please also provide:

- any changes you have made to `setup.py` or `setupext.py`

- the output of:

  ```bash
  rm -rf build
  python setup.py build
  ```

  The beginning of the build output contains lots of details about your platform that are useful for the matplotlib developers to diagnose your problem.

- your compiler version – e.g., `gcc --version`

Including this information in your first e-mail to the mailing list will save a lot of time.

You will likely get a faster response writing to the mailing list than filing a bug in the bug tracker. Most developers check the bug tracker only periodically. If your problem has been determined to be a bug and can not be quickly solved, you may be asked to file a bug in the tracker so the issue doesn’t get lost.

### 61.5 Problems with recent git versions

First make sure you have a clean build and install (see How to completely remove matplotlib), get the latest git update, install it and run a simple test script in debug mode:

```bash
rm -rf build
rm -rf /path/to/site-packages/matplotlib*
git pull
python setup.py install > build.out
python examples/pylab_examples/simple_plot.py --verbose-debug > run.out
```

and post `build.out` and `run.out` to the matplotlib-devel mailing list (please do not post git problems to the users list).
Of course, you will want to clearly describe your problem, what you are expecting and what you are getting, but often a clean build and install will help. See also *Getting help.*
## Contents

- Environment Variables
  - Setting environment variables in Linux and OS-X
    - BASH/KSH
    - CSH/TCSH
  - Setting environment variables in windows

### HOME

The user’s home directory. On Linux, ~ is shorthand for `HOME`.

### PATH

The list of directories searched to find executable programs.

### PYTHONPATH

The list of directories that is added to Python’s standard search list when importing packages and modules.

### MPLCONFIGDIR

This is the directory used to store user customizations to matplotlib, as well as some caches to improve performance. If `MPLCONFIGDIR` is not defined, `HOME/.matplotlib` is used if it is writable. Otherwise, the python standard library `tempfile.gettempdir()` is used to find a base directory in which the `matplotlib` subdirectory is created.

### MPLBACKEND

This optional variable can be set to choose the matplotlib backend. Using the `-d` command line parameter or the `use()` function will override this value. See *What is a backend?*.

### 62.1 Setting environment variables in Linux and OS-X

To list the current value of `PYTHONPATH`, which may be empty, try:
echo $PYTHONPATH

The procedure for setting environment variables in depends on what your default shell is. **BASH** seems to be the most common, but **CSH** is also common. You should be able to determine which by running at the command prompt:

```
echo $SHELL
```

### 62.1.1 BASH/KSH

To create a new environment variable:

```
export PYTHONPATH=~/.Python
```

To prepend to an existing environment variable:

```
export PATH=~/.bin:$PATH
```

The search order may be important to you, do you want ~/.bin to be searched first or last? To append to an existing environment variable:

```
export PATH=${PATH}:~/.bin
```

To make your changes available in the future, add the commands to your ~/.bashrc file.

### 62.1.2 CSH/TCSH

To create a new environment variable:

```
setenv PYTHONPATH ~/.Python
```

To prepend to an existing environment variable:

```
setenv PATH ~/.bin:$PATH
```

The search order may be important to you, do you want ~/.bin to be searched first or last? To append to an existing environment variable:

```
setenv PATH ${PATH}:~/.bin
```

To make your changes available in the future, add the commands to your ~/.cshrc file.

### 62.2 Setting environment variables in windows

Open the **Control Panel** (Start → Control Panel), start the **System** program. Click the **Advanced** tab and select the **Environment Variables** button. You can edit or add to the **User Variables**.
CHAPTER SIXTYTHREE

WORKING WITH MATPLOTLIB IN VIRTUAL ENVIRONMENTS

Contents

- Working with Matplotlib in Virtual environments
  - Introduction
  - GUI Frameworks

63.1 Introduction

When running matplotlib in a virtual environment you may discover a few issues. matplotlib itself has no issue with virtual environments. However, the GUI frameworks that matplotlib uses for interactive figures have some issues with virtual environments. Everything below assumes some familiarity with the Matplotlib backends as found in What is a backend?.

If you only use the IPython/Jupyter Notebook’s inline and notebook backends and non interactive backends you should not have any issues and can ignore everything below.

If you are using Matplotlib on OSX you may also want to consider the OSX framework FAQ.

63.2 GUI Frameworks

Interactive Matplotlib relies heavily on the interaction with external GUI frameworks.

Most GUI frameworks are not pip installable. This makes it tricky to install them within a virtual environment. This problem does not exist if you use Conda environments where you can install all Conda supported GUI frameworks directly into the environment. In regular virtualenv environment various workarounds exist. Some of these are given here:

- The TKAgg backend doesn’t require any external dependencies and is normally always available.
- The QT4 framework PySide is pip installable.
- PYQT5 is pip installable on Python 3.5.
Other frameworks are harder to install into a virtual environment. There are at least two possible ways to get access to these in a virtual environment.

One often suggested solution is to use the `--system-site-packages` option to virtualenv when creating an environment. This adds all system wide packages to the virtual environment. However, this breaks the isolation between the virtual environment and the system install. Among other issues it results in hard to debug problems with system packages shadowing the environment packages. If you use `virtualenvwrapper` this can be toggled with the `toggleglobalsitepackages` command.

Alternatively, you can manually symlink the GUI frameworks into the environment. I.e. to use PyQt5, you should symlink PyQt5 and sip from your system site packages directory into the environment taking care that the environment and the systemwide install use the same python version.
64.1 Introduction

On OSX, two different types of Python Builds exist: a regular build and a framework build. In order to interact correctly with OSX through the native GUI frameworks you need a framework build of Python. At the time of writing the `macosx` and `WXAgg` backends require a framework build to function correctly. This can result in issues for a python installation not build as a framework and may also happen in virtual envs and when using (Ana)Conda. From Matplotlib 1.5 onwards the `macosx` backend checks that a framework build is available and fails if a non framework build is found. WX has a similar check build in.

Without this check a partially functional figure is created. Among the issues with it is that it is produced in the background and cannot be put in front of any other window. Several solutions and work arounds exist see below.
64.2 Short version

64.2.1 VirtualEnv

If you are on Python 3, use venv instead of virtualenv:

```
python -m venv my-virtualenv
source my-virtualenv/bin/activate
```

Otherwise you will need one of the workarounds below.

64.2.2 Pyenv

If you are using pyenv and virtualenv you can enable your python version to be installed as a framework:

```
PYTHON_CONFIGURE_OPTS="--enable-framework" pyenv install x.x.x
```

64.2.3 Conda

The default python provided in (Ana)Conda is not a framework build. However, the Conda developers have made it easy to install a framework build in both the main environment and in Conda envs. To use this install python.app conda install python.app and use pythonw rather than python

64.3 Long version

Unfortunately virtualenv creates a non framework build even if created from a framework build of Python. As documented above you can use venv as an alternative on Python 3.

The issue has been reported on the virtualenv bug tracker here and here

Until this is fixed, one of the following workarounds can be used:

64.3.1 PYTHONHOME Function

The best known work around is to use the non virtualenv python along with the PYTHONHOME environment variable. This can be done by defining a function in your .bashrc using

```
function frameworkpython {
    if [[ ! -z "$VIRTUAL_ENV" ]]; then
        PYTHONHOME=$VIRTUAL_ENV /usr/local/bin/python "@"
    else
        /usr/local/bin/python "@"
    fi
}
```
This function can then be used in all of your virtualenvs without having to fix every single one of them.

With this in place you can run frameworkpython to get an interactive framework build within the virtualenv. To run a script you can do frameworkpython test.py where test.py is a script that requires a framework build. To run an interactive IPython session with the framework build within the virtual environment you can do frameworkpython -m IPython

**PYTHONHOME Script**

An alternative work around borrowed from the WX wiki, is to use the non virtualenv python along with the PYTHONHOME environment variable. This can be implemented in a script as below. To use this modify PYVER and PATHOPYTHON and put the script in the virtualenv bin directory i.e. PATHTOENV/bin/

```
#!/bin/bash

# what real Python executable to use
PYVER=2.7
PATHOPYTHON=/usr/local/bin/
PYTHON=${PATHOPYTHON}python${PYVER}

# find the root of the virtualenv, it should be the parent of the dir this script is in
ENV="`$PYTHON -c "import os; print(os.path.abspath(os.path.join(os.path.dirname(\"$0\"), '..', '..'))")"`

# now run Python with the virtualenv set as Python's HOME
export PYTHONHOME=$ENV
exec $PYTHON "$@
```

With this in place you can run frameworkpython as above but will need to add this script to every virtualenv

**PythonW Compiler**

In addition virtualenv-pythonw-osx provides an alternative workaround which may be used to solve the issue.
Part IV

Matplotlib AxesGrid Toolkit
The matplotlib AxesGrid toolkit is a collection of helper classes to ease displaying multiple images in matplotlib. While the aspect parameter in matplotlib adjust the position of the single axes, AxesGrid toolkit provides a framework to adjust the position of multiple axes according to their aspects.

Note: AxesGrid toolkit has been a part of matplotlib since v 0.99. Originally, the toolkit had a single namespace of axes_grid. In more recent version (since svn r8226), the toolkit has divided into two separate namespace (axes_grid1 and axisartist). While axes_grid namespace is maintained for the backward compatibility, use of axes_grid1 and axisartist is recommended.

Warning: axes_grid and axisartist (but not axes_grid1) uses a custom Axes class (derived from the mpl’s original Axes class). As a side effect, some commands (mostly tick-related) do not work. Use axes_grid1 to avoid this, or see how things are different in axes_grid and axisartist (LINK needed)
OVERVIEW OF AXESGRID TOOLKIT

65.1 What is AxesGrid toolkit?

The matplotlib AxesGrid toolkit is a collection of helper classes, mainly to ease displaying (multiple) images in matplotlib.

**Note:** AxesGrid toolkit has been a part of matplotlib since v 0.99. Originally, the toolkit had a single namespace of *axes_grid*. In more recent version (since svn r8226), the toolkit has divided into two separate namespace (*axes_grid1* and *axisartist*). While *axes_grid* namespace is maintained for the backward compatibility, use of *axes_grid1* and *axisartist* is recommended.

**Warning:** *axes_grid* and *axisartist* (but not *axes_grid1*) uses a custom Axes class (derived from the mpl’s original Axes class). As a side effect, some commands (mostly tick-related) do not work. Use *axes_grid1* to avoid this, or see how things are different in *axes_grid* and *axisartist* (LINK needed)

AxesGrid toolkit has two namespaces (*axes_grid1* and *axisartist*). *axisartist* contains custom Axes class that is meant to support for curvilinear grids (e.g., the world coordinate system in astronomy). Unlike mpl’s original Axes class which uses Axes.xaxis and Axes.yaxis to draw ticks, ticklines and etc., Axes in axisartist uses special artist (AxisArtist) which can handle tick, ticklines and etc. for curved coordinate systems.
Since it uses a special artists, some mpl commands that work on Axes.xaxis and Axes.yaxis may not work. See LINK for more detail.

`axes_grid1` is a collection of helper classes to ease displaying (multiple) images with matplotlib. In matplotlib, the axes location (and size) is specified in the normalized figure coordinates, which may not be ideal for displaying images that needs to have a given aspect ratio. For example, it helps you to have a colorbar whose height always matches that of the image. `ImageGrid`, `RGB Axes` and `AxesDivider` are helper classes that deals with adjusting the location of (multiple) Axes. They provides a framework to adjust the position of multiple axes at the drawing time. `ParasiteAxes` provides twinx(or twiny)-like features so that you can plot different data (e.g., different y-scale) in a same Axes. `AnchoredArtists` includes custom artists which are placed at some anchored position, like the legend.
65.2 AXES_GRID1

65.2.1 ImageGrid

A class that creates a grid of Axes. In matplotlib, the axes location (and size) is specified in the normalized figure coordinates. This may not be ideal for images that needs to be displayed with a given aspect ratio. For example, displaying images of a same size with some fixed padding between them cannot be easily done in matplotlib. ImageGrid is used in such case.

```python
import matplotlib.pyplot as plt
from mpl_toolkits.axes_grid1 import ImageGrid
import numpy as np

im = np.arange(100)
im.shape = 10, 10

fig = plt.figure(1, (4., 4.))
grid = ImageGrid(fig, 111,
     # similar to subplot(111)
nrows_ncols=(2, 2),  # creates 2x2 grid of axes
    axes_pad=0.1,  # pad between axes in inch.
)

for i in range(4):
    grid[i].imshow(im)  # The AxesGrid object work as a list of axes.

plt.show()
```

```

```

65.2. AXES_GRID1  1731
• The position of each axes is determined at the drawing time (see AxesDivider), so that the size of the entire grid fits in the given rectangle (like the aspect of axes). Note that in this example, the paddings between axes are fixed even if you changes the figure size.

• axes in the same column has a same axes width (in figure coordinate), and similarly, axes in the same row has a same height. The widths (height) of the axes in the same row (column) are scaled according to their view limits (xlim or ylim).

```python
import matplotlib.pyplot as plt
from mpl_toolkits.axes_grid1 import ImageGrid

def get_demo_image():
    import numpy as np
    from matplotlib.cbook import get_sample_data
    f = get_sample_data("axes_grid/bivariate_normal.npy", asfileobj=False)
    z = np.load(f)
    # z is a numpy array of 15x15
    return z, (-3, 4, -4, 3)

F = plt.figure(1, (5.5, 3.5))
grid = ImageGrid(F, 111,
                 # similar to subplot(111)
                 nrows_ncols=(1, 3),
                 axes_pad=0.1,
                 add_all=True,
                 label_mode="L",
                 )

Z, extent = get_demo_image()  # demo image

im1 = Z
im2 = Z[:, :10]
im3 = Z[:, 10:]
vmin, vmax = Z.min(), Z.max()
for i, im in enumerate([im1, im2, im3]):
    ax = grid[i]
    ax.imshow(im, origin="lower", vmin=vmin,
              vmax=vmax, interpolation="nearest")

plt.draw()
plt.show()
```
• xaxis are shared among axes in a same column. Similarly, yaxis are shared among axes in a same row. Therefore, changing axis properties (view limits, tick location, etc. either by plot commands or using your mouse in interactive backends) of one axes will affect all other shared axes.

When initialized, ImageGrid creates given number (ngrids or ncols * nrows if ngrids is None) of Axes instances. A sequence-like interface is provided to access the individual Axes instances (e.g., grid[0] is the first Axes in the grid. See below for the order of axes).

AxesGrid takes following arguments,

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fig</td>
<td></td>
<td></td>
</tr>
<tr>
<td>rect</td>
<td></td>
<td></td>
</tr>
<tr>
<td>nrows_ncols</td>
<td></td>
<td>number of rows and cols. e.g., (2,2)</td>
</tr>
<tr>
<td>ngrids</td>
<td>None</td>
<td>number of grids. nrows x ncols if None</td>
</tr>
<tr>
<td>direction</td>
<td>“row”</td>
<td>increasing direction of axes number. [row</td>
</tr>
<tr>
<td>axes_pad</td>
<td>0.02</td>
<td>pad between axes in inches</td>
</tr>
<tr>
<td>add_all</td>
<td>True</td>
<td>Add axes to figures if True</td>
</tr>
<tr>
<td>share_all</td>
<td>False</td>
<td>xaxis &amp; yaxis of all axes are shared if True</td>
</tr>
<tr>
<td>aspect</td>
<td>True</td>
<td>aspect of axes</td>
</tr>
<tr>
<td>label_mode</td>
<td>“L”</td>
<td>location of tick labels thaw will be displayed. “1” (only the lower left axes), “L” (left most and bottom most axes), or “all”.</td>
</tr>
<tr>
<td>cbar_mode</td>
<td>None</td>
<td>[None</td>
</tr>
<tr>
<td>cbar_location</td>
<td>right</td>
<td>[right</td>
</tr>
<tr>
<td>cbar_pad</td>
<td>None</td>
<td>pad between image axes and colorbar axes</td>
</tr>
<tr>
<td>cbar_size</td>
<td>“5%”</td>
<td>size of the colorbar</td>
</tr>
<tr>
<td>axes_class</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
rect specifies the location of the grid. You can either specify coordinates of the rectangle to be used (e.g., (0.1, 0.1, 0.8, 0.8) as in the Axes), or the subplot-like position (e.g., “121”).

direction means the increasing direction of the axes number.

aspect By default (False), widths and heights of axes in the grid are scaled independently. If True, they are scaled according to their data limits (similar to aspect parameter in mpl).

share_all if True, xaxis and yaxis of all axes are shared.

direction direction of increasing axes number. For “row”,

\[
\begin{array}{cc}
\text{grid[0]} & \text{grid[1]} \\
\text{grid[2]} & \text{grid[3]} \\
\end{array}
\]

For “column”,

\[
\begin{array}{cc}
\text{grid[0]} & \text{grid[2]} \\
\text{grid[1]} & \text{grid[3]} \\
\end{array}
\]

You can also create a colorbar (or colorbars). You can have colorbar for each axes (cbar_mode=”each”), or you can have a single colorbar for the grid (cbar_mode=”single”). The colorbar can be placed on your right, or top. The axes for each colorbar is stored as a cbar_axes attribute.

The examples below show what you can do with AxesGrid.

65.2.2 AxesDivider

Behind the scene, the ImageGrid class and the RGBAaxes class utilize the AxesDivider class, whose role is to calculate the location of the axes at drawing time. While a more about the AxesDivider is (will be) explained in (yet to be written) AxesDividerGuide, direct use of the AxesDivider class will not be necessary for most users. The axes_divider module provides a helper function make_axes_locatable, which can be useful. It takes a existing axes instance and create a divider for it.

ax = subplot(1,1,1)
divider = make_axes_locatable(ax)

make_axes_locatable returns an instance of the AxesLocator class, derived from the Locator. It provides append_axes method that creates a new axes on the given side of (“top”, “right”, “bottom” and “left”) of the original axes.
65.2.3 colorbar whose height (or width) in sync with the master axes

```python
import matplotlib.pyplot as plt
from mpl_toolkits.axes_grid1 import make_axes_locatable
import numpy as np

ax = plt.subplot(111)
im = ax.imshow(np.arange(100).reshape((10,10)))

# create an axes on the right side of ax. The width of cax will be 5%
# of ax and the padding between cax and ax will be fixed at 0.05 inch.
divider = make_axes_locatable(ax)
cax = divider.append_axes("right", size="5\%", pad=0.05)

plt.colorbar(im, cax=cax)
```

scatter_hist.py with AxesDivider

The “scatter_hist.py” example in mpl can be rewritten using `make_axes_locatable`.

```python
axScatter = subplot(111)
axScatter.scatter(x, y)
axScatter.set_aspect(1.)
```
# create new axes on the right and on the top of the current axes.
divider = make_axes_locatable(axScatter)
axHistx = divider.append_axes("top", size=1.2, pad=0.1, sharex=axScatter)
axHisty = divider.append_axes("right", size=1.2, pad=0.1, sharey=axScatter)

# the scatter plot:
# histograms
bins = np.arange(-lim, lim + binwidth, binwidth)
axHistx.hist(x, bins=bins)
axHisty.hist(y, bins=bins, orientation='horizontal')

See the full source code below.

The scatter_hist using the AxesDivider has some advantage over the original scatter_hist.py in mpl. For example, you can set the aspect ratio of the scatter plot, even with the x-axis or y-axis is shared accordingly.
65.2.4 ParasiteAxes

The ParasiteAxes is an axes whose location is identical to its host axes. The location is adjusted in the
drawing time, thus it works even if the host change its location (e.g., images).

In most cases, you first create a host axes, which provides a few method that can be used to create parasite
axes. They are twinx, twiny (which are similar to twinx and twiny in the matplotlib) and twin. twin takes
an arbitrary transformation that maps between the data coordinates of the host axes and the parasite axes.
draw method of the parasite axes are never called. Instead, host axes collects artists in parasite axes and
draw them as if they belong to the host axes, i.e., artists in parasite axes are merged to those of the host axes
and then drawn according to their zorder. The host and parasite axes modifies some of the axes behavior.
For example, color cycle for plot lines are shared between host and parasites. Also, the legend command in
host, creates a legend that includes lines in the parasite axes. To create a host axes, you may use host_subplot
or host_axes command.

Example 1. twinx

```python
from mpl_toolkits.axes_grid1 import host_subplot
import matplotlib.pyplot as plt

host = host_subplot(111)
par = host.twinx()

host.set_xlabel("Distance")
host.set_ylabel("Density")
par.set_ylabel("Temperature")

p1, = host.plot([0, 1, 2], [0, 1, 2], label="Density")
p2, = par.plot([0, 1, 2], [0, 3, 2], label="Temperature")

leg = plt.legend()

host.yaxis.get_label().set_color(p1.get_color())
leg.texts[0].set_color(p1.get_color())

par.yaxis.get_label().set_color(p2.get_color())
leg.texts[1].set_color(p2.get_color())

plt.show()
```
Example 2. `twin`

twin without a transform argument treat the parasite axes to have a same data transform as the host. This can be useful when you want the top(or right)-axis to have different tick-locations, tick-labels, or tick-formatter for bottom(or left)-axis.

```
ax2 = ax.twin() # now, ax2 is responsible for "top" axis and "right" axis
ax2.set_xticks([0., .5*np.pi, np.pi, 1.5*np.pi, 2*np.pi])
ax2.set_xticklabels(["0", r"$\frac{1}{2}\pi$", r"$\pi$", r"$\frac{3}{2}\pi$", r"$2\pi$"])
```
A more sophisticated example using twin. Note that if you change the x-limit in the host axes, the x-limit of the parasite axes will change accordingly.
65.2.5 AnchoredArtists

It's a collection of artists whose location is anchored to the (axes) bbox, like the legend. It is derived from OffsetBox in mpl, and artist need to be drawn in the canvas coordinate. But, there is a limited support for an arbitrary transform. For example, the ellipse in the example below will have width and height in the data coordinate.

```python
import matplotlib.pyplot as plt

def draw_text(ax):
    from matplotlib.offsetbox import AnchoredText
    at = AnchoredText("Figure 1a", loc=2, prop=dict(size=8), frameon=True, )
    at.patch.set_boxstyle("round,pad=0.,rounding_size=0.2")
    ax.add_artist(at)

    at2 = AnchoredText("Figure 1(b)", loc=3, prop=dict(size=8), frameon=True,
        bbox_to_anchor=(0., 1.),
        bbox_transform=ax.transAxes
    )
    at2.patch.set_boxstyle("round,pad=0.,rounding_size=0.2")
```

Chapter 65. Overview of AxesGrid toolkit
ax.add_artist(at2)

def draw_circle(ax):
    """circle in the canvas coordinate"""
    from mpl_toolkits.axes_grid1.anchored_artists import AnchoredDrawingArea
    from matplotlib.patches import Circle
    ada = AnchoredDrawingArea(20, 20, 0, 0,
                              loc=1, pad=0., frameon=False)
    p = Circle((10, 10), 10)
    ada.da.add_artist(p)
    ax.add_artist(ada)

    def draw_ellipse(ax):
        """draw an ellipse of width=0.1, height=0.15 in the data coordinate"""
        ae = AnchoredEllipse(ax.transData, width=0.1, height=0.15, angle=0.,
                              loc=3, pad=0.5, borderpad=0.4, frameon=True)

        ax.add_artist(ae)

    def draw_sizebar(ax):
        """draw a horizontal bar with length of 0.1 in Data coordinate
        (ax.transData) with a label underneath."""
        asb = AnchoredSizeBar(ax.transData,
                              0.1,
                              r""""1$^\prime$"
                              , loc=8,
                              pad=0.1, borderpad=0.5, sep=5,
                              frameon=False)

        ax.add_artist(asb)

if 1:
    ax = plt.gca()
    ax.set_aspect(1.)

draw_text(ax)
draw_circle(ax)
draw_ellipse(ax)
draw_sizebar(ax)

plt.show()
65.2.6 InsetLocator

mpl_toolkits.axes_grid.inset_locator provides helper classes and functions to place your (inset) axes at the anchored position of the parent axes, similarly to AnchoredArtist.

Using mpl_toolkits.axes_grid.inset_locator.inset_axes(), you can have inset axes whose size is either fixed, or a fixed proportion of the parent axes. For example:

```python
inset_axes = inset_axes(parent_axes,
                         width="30%",  # width = 30% of parent_bbox
data_scale=0.5,  # zoom = 0.5
                         height=1.,    # height : 1 inch
                         loc=3)
```

creates an inset axes whose width is 30% of the parent axes and whose height is fixed at 1 inch.

You may create an inset whose size is determined so that the data scale of the inset axes to be that of the parent axes multiplied by some factor. For example,

```python
inset_axes = zoomed_inset_axes(ax,
                                0.5,    # zoom = 0.5
                                loc=1)
```

creates an inset axes whose data scale is half of the parent axes. Here is complete examples.
For example, `zoomed_inset_axes()` can be used when you want the inset represents the zoom-up of the small portion in the parent axes. And `mpl_toolkits/axes_grid/inset_locator` provides a helper function `mark_inset()` to mark the location of the area represented by the inset axes.

```python
import matplotlib.pyplot as plt
from mpl_toolkits.axes_grid1.inset_locator import zoomed_inset_axes
from mpl_toolkits.axes_grid1.inset_locator import mark_inset
import numpy as np
def get_demo_image():
    from matplotlib.cbook import get_sample_data
    import numpy as np
    f = get_sample_data("axes_grid/bivariate_normal.npy", asfileobj=False)
    z = np.load(f)
    # z is a numpy array of 15x15
    return z, (-3, 4, -4, 3)

fig, ax = plt.subplots(figsize=[5, 4])

# prepare the demo image
Z, extent = get_demo_image()
Z2 = np.zeros([150, 150], dtype="d")
ny, nx = Z.shape
Z2[30:30 + ny, 30:30 + nx] = Z

# extent = [-3, 4, -4, 3]
ax.imshow(Z2, extent=extent, interpolation="nearest",
          origin="lower")

axins = zoomed_inset_axes(ax, 6, loc=1)  # zoom = 6
axins.imshow(Z2, extent=extent, interpolation="nearest",
             origin="lower")
```

65.2. AXES_GRID1
RGB Axes

RGBAxes is a helper class to conveniently show RGB composite images. Like ImageGrid, the location of axes are adjusted so that the area occupied by them fits in a given rectangle. Also, the xaxis and yaxis of each axes are shared.
from mpl_toolkits.axes_grid1.axes_rgb import RGBAxes

fig = plt.figure(1)
ax = RGBAxes(fig, [0.1, 0.1, 0.8, 0.8])

r, g, b = get_rgb()  # r,g,b are 2-d images
ax.imshow_rgb(r, g, b,
              origin="lower", interpolation="nearest")

65.3 AXISARTIST

65.3.1 AxisArtist

AxisArtist module provides a custom (and very experimental) Axes class, where each axis (left, right, top and bottom) have a separate artist associated which is responsible to draw axis-line, ticks, ticklabels, label. Also, you can create your own axis, which can pass through a fixed position in the axes coordinate, or a fixed position in the data coordinate (i.e., the axis floats around when viewlimit changes).

The axes class, by default, have its xaxis and yaxis invisible, and has 4 additional artists which are responsible to draw axis in “left”, “right”, “bottom” and “top”. They are accessed as ax.axis["left"], ax.axis["right"], and so on, i.e., ax.axis is a dictionary that contains artists (note that ax.axis is still a callable methods and it behaves as an original Axes.axis method in mpl).
To create an axes,

```python
import mpl_toolkits.axisartist as AA
fig = plt.figure(1)
ax = AA.Axes(fig, [0.1, 0.1, 0.8, 0.8])
fig.add_axes(ax)
```
or to create a subplot

```python
ax = AA.Subplot(fig, 111)
fig.add_subplot(ax)
```

For example, you can hide the right, and top axis by

```python
ax.axis["right"].set_visible(False)
ax.axis["top"].set_visible(False)
```

It is also possible to add an extra axis. For example, you may have an horizontal axis at y=0 (in data coordinate).

```python
import matplotlib.pyplot as plt
import mpl_toolkits.axisartist as AA

fig = plt.figure(1)
fig.subplots_adjust(right=0.85)
ax = AA.Subplot(fig, 1, 1, 1)
fig.add_subplot(ax)

# make some axis invisible
ax.axis["bottom", "top", "right"].set_visible(False)

# make an new axis along the first axis (x-axis) which pass
```
# through y=0.
ax.axis["y=0"] = ax.new_floating_axis(nth_coord=0, value=0,
    axis_direction="bottom")
ax.axis["y=0"].toggle(all=True)
ax.axis["y=0"].label.set_text("y = 0")
ax.set_ymargin(-2, 4)
plt.show()
host = host_subplot(111, axes_class=AA.Axes)

Here is an example that uses parasiteAxes.

65.3.2 Curvilinear Grid

The motivation behind the AxisArtist module is to support curvilinear grid and ticks.
See `AXISARTIST namespace` for more details.

### 65.3.3 Floating Axes

This also support a Floating Axes whose outer axis are defined as floating axis.
66.1 AxesDivider

The axes_divider module provides helper classes to adjust the axes positions of sets of images in the drawing time.

- **axes_size** provides a class of units that the size of each axes will be determined. For example, you can specify a fixed size
- **Divider** this is the class that is used to calculate the axes position. It divides the given rectangular area into several areas. You initialize the divider by setting the horizontal and vertical list of sizes that the division will be based on. You then use the new_locator method, whose return value is a callable object that can be used to set the axes_locator of the axes.

You first initialize the divider by specifying its grids, i.e., horizontal and vertical.

for example,

```python
rect = [0.2, 0.2, 0.6, 0.6]
horiz=[h0, h1, h2, h3]
vert=[v0, v1, v2]
divider = Divider(fig, rect, horiz, vert)
```

where, `rect` is a bounds of the box that will be divided and `h0...h3, v0...v2` need to be an instance of classes in the `axes_size`. They have `get_size` method that returns a tuple of two floats. The first float is the relative size, and the second float is the absolute size. Consider a following grid.

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>v0</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>v1</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>h0,v2</td>
<td>h1</td>
<td>h2</td>
<td>h3</td>
</tr>
</tbody>
</table>

- `v0 => 0, 2`
- `v1 => 2, 0`
- `v2 => 3, 0`
The height of the bottom row is always 2 (axes_divider internally assumes that the unit is inch). The first
and the second rows with height ratio of 2:3. For example, if the total height of the grid 6, then the first and
second row will each occupy 2/(2+3) and 3/(2+3) of (6-1) inches. The widths of columns (horiz) will be
similarly determined. When aspect ratio is set, the total height (or width) will be adjusted accordingly.

The mpl_toolkits.axes_grid.axes_size contains several classes that can be used to set the horizontal
and vertical configurations. For example, for the vertical configuration above will be:

```python
from mpl_toolkits.axes_grid.axes_size import Fixed, Scaled
vert = [Fixed(2), Scaled(2), Scaled(3)]
```

After you set up the divider object, then you create a locator instance which will be given to the axes:

```python
locator = divider.new_locator(nx=0, ny=1)
ax.set_axes_locator(locator)
```

The return value of the new_locator method is a instance of the AxesLocator class. It is a callable object
that returns the location and size of the cell at the first column and the second row. You may create a locator
that spans over multiple cells:

```python
locator = divider.new_locator(nx=0, nx=2, ny=1)
```

The above locator, when called, will return the position and size of the cells spanning the first and second
column and the first row. You may consider it as [0:2, 1].

See the example,

```python
import mpl_toolkits.axes_grid.axes_size as Size
from mpl_toolkits.axes_grid import Divider
import matplotlib.pyplot as plt

fig1 = plt.figure(1, (5.5, 4.))
# the rect parameter will be ignore as we will set axes_locator
rect = (0.1, 0.1, 0.8, 0.8)
ax = [fig1.add_axes(rect, label="%d"%i) for i in range(4)]

horiz = [Size.Scaled(1.5), Size.Fixed(.5), Size.Scaled(1.),
         Size.Scaled(.5)]

vert = [Size.Scaled(1.), Size.Fixed(.5), Size.Scaled(1.5)]

# divide the axes rectangle into grid whose size is specified by horiz * vert
divider = Divider(fig1, rect, horiz, vert, aspect=False)

ax[0].set_axes_locator(divider.new_locator(nx=0, ny=0))
ax[1].set_axes_locator(divider.new_locator(nx=0, ny=2))
ax[2].set_axes_locator(divider.new_locator(nx=2, ny=2))
ax[3].set_axes_locator(divider.new_locator(nx=2, nx1=4, ny=0))

for ax1 in ax:
    plt.setp(ax1.get_xticklabels()+ax1.get_yticklabels(),
             visible=False)
```

1752 Chapter 66. The Matplotlib AxesGrid Toolkit User’s Guide
You can adjust the size of the each axes according to their x or y data limits (AxesX and AxesY), similar to the axes aspect parameter.

```python
import mpl_toolkits.axes_grid.axes_size as Size
from mpl_toolkits.axes_grid import Divider
import matplotlib.pyplot as plt

fig1 = plt.figure(1, (5.5, 4))

# the rect parameter will be ignore as we will set axes_locator
rect = (0.1, 0.1, 0.8, 0.8)
ax = [fig1.add_axes(rect, label='%.1d' % i) for i in range(4)]

horiz = [Size.AxesX(ax[0]), Size.Fixed(.5), Size.AxesX(ax[1])]
vert = [Size.AxesY(ax[0]), Size.Fixed(.5), Size.AxesY(ax[2])]

# divide the axes rectangle into grid whose size is specified by horiz * vert
divider = Divider(fig1, rect, horiz, vert, aspect=False)

ax[0].set_axes_locator(divider.new_locator(nx=0, ny=0))
ax[1].set_axes_locator(divider.new_locator(nx=2, ny=0))
```
66.2 AXISARTIST namespace

The AxisArtist namespace includes a derived Axes implementation. The biggest difference is that the artists responsible to draw axis line, ticks, ticklabel and axis labels are separated out from the mpl’s Axis class, which are much more than artists in the original mpl. This change was strongly motivated to support curvi-linear grid. Here are a few things that mpl_toolkits.axisartist.Axes is different from original Axes from mpl.
• Axis elements (axis line(spine), ticks, ticklabel and axis labels) are drawn by a AxisArtist instance. Unlike Axis, left, right, top and bottom axis are drawn by separate artists. And each of them may have different tick location and different tick labels.

• gridlines are drawn by a Gridlines instance. The change was motivated that in curvilinear coordinate, a gridline may not cross axis-lines (i.e., no associated ticks). In the original Axes class, gridlines are tied to ticks.

• ticklines can be rotated if necessary (i.e, along the gridlines)

In summary, all these changes was to support

• a curvilinear grid.

• a floating axis

mpl_toolkits.axisartist.Axes class defines a axis attribute, which is a dictionary of AxisArtist instances. By default, the dictionary has 4 AxisArtist instances, responsible for drawing of left, right, bottom and top axis. xaxis and yaxis attributes are still available, however they are set to not visible. As separate artists are used for rendering axis, some axis-related method in mpl may have no effect. In addition to AxisArtist instances, the mpl_toolkits.axisartist.Axes will have gridlines attribute (Gridlines), which obviously draws grid lines.

In both AxisArtist and Gridlines, the calculation of tick and grid location is delegated to an instance of
Matplotlib, Release 2.0.0

GridHelper class. mpl_toolkits.axisartist.Axes class uses GridHelperRectlinear as a grid helper. The GridHelperRectlinear class is a wrapper around the xaxis and yaxis of mpl’s original Axes, and it was meant to work as the way how mpl’s original axes works. For example, tick location changes using set_ticks method and etc. should work as expected. But change in artist properties (e.g., color) will not work in general, although some effort has been made so that some often-change attributes (color, etc.) are respected.

### 66.2.1 AxisArtist

AxisArtist can be considered as a container artist with following attributes which will draw ticks, labels, etc.

- **line**
- **major_ticks, major_ticklabels**
- **minor_ticks, minor_ticklabels**
- **offsetText**
- **label**

**line**

Derived from Line2d class. Responsible for drawing a spinal(?) line.

**major_ticks, minor_ticks**

Derived from Line2d class. Note that ticks are markers.

**major_ticklabels, minor_ticklabels**

Derived from Text. Note that it is not a list of Text artist, but a single artist (similar to a collection).

**axislabel**

Derived from Text.

### Default AxisArtists

By default, following for axis artists are defined:

```python
ax.axis["left"], ax.axis["bottom"], ax.axis["right"], ax.axis["top"]
```

The ticklabels and axislabel of the top and the right axis are set to not visible.

For example, if you want to change the color attributes of major_ticklabels of the bottom x-axis
ax.axis["bottom"].major_ticklabels.set_color("b")

Similarly, to make ticklabels invisible

ax.axis["bottom"].major_ticklabels.set_visible(False)

AxisArtist provides a helper method to control the visibility of ticks, ticklabels, and label. To make ticklabel invisible,

ax.axis["bottom"].toggle(ticklabels=False)

To make all of ticks, ticklabels, and (axis) label invisible

ax.axis["bottom"].toggle(all=False)

To turn all off but ticks on

ax.axis["bottom"].toggle(all=False, ticks=True)

To turn all on but (axis) label off

ax.axis["bottom"].toggle(all=True, label=False)

ax.axis’s __getitem__ method can take multiple axis names. For example, to turn ticklabels of “top” and “right” axis on,

ax.axis["top","right"].toggle(ticklabels=True)

Note that ‘ax.axis["top","right"]’ returns a simple proxy object that translate above code to something like below.

for n in ["top","right"]:
    ax.axis[n].toggle(ticklabels=True)

So, any return values in the for loop are ignored. And you should not use it anything more than a simple method.

Like the list indexing ”:” means all items, i.e.,

ax.axis[:].major_ticks.set_color("r")

changes tick color in all axis.

66.2.2 HowTo

1. Changing tick locations and label.

   Same as the original mpl’s axes:
2. Changing axis properties like color, etc.
   Change the properties of appropriate artists. For example, to change the color of the ticklabels:
   ```python
   ax.axis["left"].major_ticklabels.set_color("r")
   ```

3. To change the attributes of multiple axis:
   ```python
   ax.axis["left","bottom"].major_ticklabels.set_color("r")
   or to change the attributes of all axis:
   ```python
   ax.axis[:].major_ticklabels.set_color("r")
   ```

4. To change the tick size (length), you need to use `axis.major_ticks.set_ticksize` method. To change the direction of the ticks (ticks are in opposite direction of ticklabels by default), use `axis.major_ticks.set_tick_out` method.
   To change the pad between ticks and ticklabels, use `axis.major_ticklabels.set_pad` method.
   To change the pad between ticklabels and axis label, `axis.label.set_pad` method.

66.2.3 Rotation and Alignment of TickLabels

This is also quite different from the original mpl and can be confusing. When you want to rotate the ticklabels, first consider using "set_axis_direction" method.

```python
ax1.axis["left"].major_ticklabels.set_axis_direction("top")
ax1.axis["right"].label.set_axis_direction("left")
```

The parameter for `set_axis_direction` is one of ["left", “right”, “bottom”, “top”].
You must understand some underlying concept of directions.
1. There is a reference direction which is defined as the direction of the axis line with increasing coordinate. For example, the reference direction of the left x-axis is from bottom to top.

![Diagram showing the reference direction for the left x-axis]

The direction, text angle, and alignments of the ticks, ticklabels and axis-label is determined with respect to the reference direction.

2. `ticklabel_direction` is either the right-hand side (+) of the reference direction or the left-hand side (-).

![Diagram showing `ticklabel_direction` positive and negative]

3. Same for the `label_direction`.

![Diagram showing `label_direction` positive and negative]
4. ticks are by default drawn toward the opposite direction of the ticklabels.

5. text rotation of ticklabels and label is determined in reference to the ticklabel_direction or label_direction, respectively. The rotation of ticklabels and label is anchored.

![Diagram showing axis direction and text rotation](image)

On the other hand, there is a concept of "axis_direction". This is a default setting of above properties for each, "bottom", "left", "top", and "right" axis.

<table>
<thead>
<tr>
<th></th>
<th>left</th>
<th>bottom</th>
<th>right</th>
<th>top</th>
</tr>
</thead>
<tbody>
<tr>
<td>axislabel direction</td>
<td>--</td>
<td>+</td>
<td>+</td>
<td>--</td>
</tr>
<tr>
<td>axislabel rotation</td>
<td>180</td>
<td>0</td>
<td>0</td>
<td>180</td>
</tr>
<tr>
<td>axislabel va</td>
<td>center</td>
<td>top</td>
<td>center</td>
<td>bottom</td>
</tr>
<tr>
<td>axislabel ha</td>
<td>right</td>
<td>center</td>
<td>right</td>
<td>center</td>
</tr>
<tr>
<td>ticklabel direction</td>
<td>--</td>
<td>+</td>
<td>+</td>
<td>--</td>
</tr>
<tr>
<td>ticklabels rotation</td>
<td>90</td>
<td>0</td>
<td>-90</td>
<td>180</td>
</tr>
<tr>
<td>ticklabel ha</td>
<td>right</td>
<td>center</td>
<td>right</td>
<td>center</td>
</tr>
<tr>
<td>ticklabel va</td>
<td>center</td>
<td>baseline</td>
<td>center</td>
<td>baseline</td>
</tr>
</tbody>
</table>

And, 'set_axis_direction("top")' means to adjust the text rotation etc, for settings suitable for "top" axis. The concept of axis direction can be more clear with curved axis.
The axis_direction can be adjusted in the AxisArtist level, or in the level of its child artists, i.e., ticks, ticklabels, and axis-label.

```python
ax1.axis["left"].set_axis_direction("top")
```

changes axis_direction of all the associated artist with the “left” axis, while

```python
ax1.axis["left"].major_ticklabels.set_axis_direction("top")
```

changes the axis_direction of only the major_ticklabels. Note that set_axis_direction in the AxisArtist level changes the ticklabel_direction and label_direction, while changing the axis_direction of ticks, ticklabels, and axis-label does not affect them.

If you want to make ticks outward and ticklabels inside the axes, use invert_ticklabel_direction method.

```python
ax.axis[:].invert_ticklabel_direction()
```

A related method is “set_tick_out”. It makes ticks outward (as a matter of fact, it makes ticks toward the opposite direction of the default direction).

```python
ax.axis[:].major_ticks.set_tick_out(True)
```
So, in summary,

- **AxisArtist’s methods**
  - set_axis_direction: “left”, “right”, “bottom”, or “top”
  - set_ticklabel_direction: “+” or “-”
  - set_axislabel_direction: “+” or “-”
  - invert_ticklabel_direction

- **Ticks’ methods (major_ticks and minor_ticks)**
  - set_tick_out: True or False
  - set_ticksize: size in points

- **TickLabels’ methods (major_ticklabels and minor_ticklabels)**
  - set_axis_direction: “left”, “right”, “bottom”, or “top”
  - set_rotation: angle with respect to the reference direction
  - set_ha and set_va: see below

- **AxisLabels’ methods (label)**
  - set_axis_direction: “left”, “right”, “bottom”, or “top”
  - set_rotation: angle with respect to the reference direction
  - set_ha and set_va

**Adjusting ticklabels alignment**

Alignment of TickLabels are treated specially. See below
Adjusting pad

To change the pad between ticks and ticklabels

```
ax.axis["left"].major_ticklabels.set_pad(10)
```

Or ticklabels and axis-label

```
ax.axis["left"].label.set_pad(10)
```
66.2.4 GridHelper

To actually define a curvilinear coordinate, you have to use your own grid helper. A generalised version of grid helper class is supplied and this class should suffice in most of cases. A user may provide two functions which defines a transformation (and its inverse pair) from the curved coordinate to (rectilinear) image coordinate. Note that while ticks and grids are drawn for curved coordinate, the data transform of the axes itself (ax.transData) is still rectilinear (image) coordinate.

```python
from mpl_toolkits.axisartist.grid_helper_curvelinear import GridHelperCurveLinear
from mpl_toolkits.axisartist import Subplot

# from curved coordinate to rectlinear coordinate.
def tr(x, y):
    x, y = np.asarray(x), np.asarray(y)
    return x, y-x

# from rectlinear coordinate to curved coordinate.
def inv_tr(x, y):
    x, y = np.asarray(x), np.asarray(y)
    return x, y+x

grid_helper = GridHelperCurveLinear((tr, inv_tr))

ax1 = Subplot(fig, 1, 1, 1, grid_helper=grid_helper)

fig.add_subplot(ax1)
```

You may use matplotlib’s Transform instance instead (but a inverse transformation must be defined). Often, coordinate range in a curved coordinate system may have a limited range, or may have cycles. In those cases, a more customized version of grid helper is required.

```python
import mpl_toolkits.axisartist.angle_helper as angle_helper

# PolarAxes.PolarTransform takes radian. However, we want our coordinate # system in degree
```
tr = Affine2D().scale(np.pi/180., 1.) + PolarAxes.PolarTransform()

# extreme finder : find a range of coordinate.
# 20, 20 : number of sampling points along x, y direction
# The first coordinate (longitude, but theta in polar)
# has a cycle of 360 degree.
# The second coordinate (latitude, but radius in polar) has a minimum of 0
extreme_finder = angle_helper.ExtremeFinderCycle(20, 20,
    lon_cycle = 360,
    lat_cycle = None,
    lon_minmax = None,
    lat_minmax = (0, np.inf),
)

# Find a grid values appropriate for the coordinate (degree,
# minute, second). The argument is a approximate number of grids.
grid_locator1 = angle_helper.LocatorDMS(12)

# And also uses an appropriate formatter. Note that, the
# acceptable Locator and Formatter class is a bit different than
# that of mpl's, and you cannot directly use mpl's Locator and
# Formatter here (but may be possible in the future).
tick_formatter1 = angle_helper.FormatterDMS()

grid_helper = GridHelperCurveLinear(tr,
    extreme_finder=extreme_finder,
    grid_locator1=grid_locator1,
    tick_formatter1=tick_formatter1
)

Again, the transData of the axes is still a rectilinear coordinate (image coordinate). You may manually do conversion between two coordinates, or you may use Parasite Axes for convenience.:

ax1 = SubplotHost(fig, 1, 2, 2, grid_helper=grid_helper)

# A parasite axes with given transform
ax2 = ParasiteAxesAuxTrans(ax1, tr, "equal")
# note that ax2.transData == tr + ax1.transData
# Anything you draw in ax2 will match the ticks and grids of ax1.
ax1.parasites.append(ax2)
66.2.5 FloatingAxis

A floating axis is an axis one of whose data coordinate is fixed, i.e., its location is not fixed in Axes coordinate but changes as axes data limits changes. A floating axis can be created using `new_floating_axis` method. However, it is your responsibility that the resulting AxisArtist is properly added to the axes. A recommended way is to add it as an item of Axes’s axis attribute:

```python
# floating axis whose first (index starts from 0) coordinate
# (theta) is fixed at 60

ax1.axis["lat"] = axis = ax1.new_floating_axis(0, 60)
axis.label.set_text(r"$\theta = 60^\circ$")
axis.label.set_visible(True)
```

See the first example of this page.

66.2.6 Current Limitations and TODO’s

The code need more refinement. Here is a incomplete list of issues and TODO’s

- No easy way to support a user customized tick location (for curvilinear grid). A new Locator class needs to be created.
- FloatingAxis may have coordinate limits, e.g., a floating axis of x = 0, but y only spans from 0 to 1.
- The location of axislabel of FloatingAxis needs to be optionally given as a coordinate value. ex, a floating axis of x=0 with label at y=1
67.1 `mpl_toolkits.axes_grid.axes_size`

```python
>>> s = Fraction(0.3, AxesX(ax))
```

```python
class mpl_toolkits.axes_grid.axes_size.Fixed(fixed_size)
    Simple fixed size with absolute part = fixed_size and relative part = 0
```

```python
class mpl_toolkits.axes_grid.axes_size.Scaled(scalable_size)
    Simple scaled (?) size with absolute part = 0 and relative part = scalable_size
```

```python
class mpl_toolkits.axes_grid.axes_size.AxesX(axes, aspect=1.0, ref_ax=None)
    Scaled size whose relative part corresponds to the data width of the axes multiplied by the aspect.
```

```python
class mpl_toolkits.axes_grid.axes_size.AxesY(axes, aspect=1.0, ref_ax=None)
    Scaled size whose relative part corresponds to the data height of the axes multiplied by the aspect.
```

```python
class mpl_toolkits.axes_grid.axes_size.MaxWidth(artist_list)
    Size whose absolute part is the largest width of the given artist_list.
```

```python
class mpl_toolkits.axes_grid.axes_size.MaxHeight(artist_list)
    Size whose absolute part is the largest height of the given artist_list.
```

```python
class mpl_toolkits.axes_grid.axes_size.Fraction(fraction, ref_size)
    An instance whose size is a fraction of the ref_size.
```

```python
>>> a = Size.from_any(1.2) # => Size.Fixed(1.2)
>>> Size.from_any("50\%", a) # => Size.Fraction(0.5, a)
```
67.2 `mpl_toolkits.axes_grid.axes_divider`

class `mpl_toolkits.axes_grid.axes_divider.Divider(fig, pos, horizontal, vertical, aspect=None, anchor='C')`

This is the class that is used calculates the axes position. It divides the given rectangular area into several sub-rectangles. You initialize the divider by setting the horizontal and vertical lists of sizes (`mpl_toolkits.axes_grid.axes_size`) that the division will be based on. You then use the new_locator method to create a callable object that can be used as the axes_locator of the axes.

Parameters

**fig** : Figure

**pos** : tuple of 4 floats

position of the rectangle that will be divided

**horizontal** : list of `axes_size`

sizes for horizontal division

**vertical** : list of `axes_size`

sizes for vertical division

**aspect** : bool

if True, the overall rectangular area is reduced so that the relative part of the horizontal and vertical scales have the same scale.

**anchor** : {'C', 'SW', 'S', 'SE', 'E', 'NE', 'N', 'NW', 'W'}

placement of the reduced rectangle when `aspect` is True

`add_auto_adjustable_area(use_axes, pad=0.1, adjust_dirs=None)`

`append_size(position, size)`

`get_anchor()`

return the anchor

`get_aspect()`

return aspect

`get_horizontal()`

return horizontal sizes

`get_horizontal_sizes(renderer)`

`get_locator()`

`get_position()`

return the position of the rectangle.
get_position_runtime(ax, renderer)

get_vertical()
    return vertical sizes

get_vertical_sizes(renderer)

gerget_vsize_hsize()

locate(nx, ny, nx1=None, ny1=None, axes=None, renderer=None)

    Parameters nx, nx1 : int
        Integers specifying the column-position of the cell. When nx1 is None, a
        single nx-th column is specified. Otherwise location of columns spanning
        between nx to nx1 (but excluding nx1-th column) is specified.

    ny, ny1 : int
        Same as nx and nx1, but for row positions.

    axes

    renderer

new_locator(nx, ny, nx1=None, ny1=None)
    Returns a new locator (mpl_toolkits.axes_grid.axes_divider.AxesLocator) for spec-
    ified cell.

    Parameters nx, nx1 : int
        Integers specifying the column-position of the cell. When nx1 is None, a
        single nx-th column is specified. Otherwise location of columns spanning
        between nx to nx1 (but excluding nx1-th column) is specified.

    ny, ny1 : int
        Same as nx and nx1, but for row positions.

set_anchor(anchor)

    Parameters anchor : {'C', 'SW', 'S', 'SE', 'E', 'NE', 'N', 'NW', 'W'}
        anchor position
<table>
<thead>
<tr>
<th>value</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘C’</td>
<td>Center</td>
</tr>
<tr>
<td>‘SW’</td>
<td>bottom left</td>
</tr>
<tr>
<td>‘S’</td>
<td>bottom</td>
</tr>
<tr>
<td>‘SE’</td>
<td>bottom right</td>
</tr>
<tr>
<td>‘E’</td>
<td>right</td>
</tr>
<tr>
<td>‘NE’</td>
<td>top right</td>
</tr>
<tr>
<td>‘N’</td>
<td>top</td>
</tr>
<tr>
<td>‘NW’</td>
<td>top left</td>
</tr>
<tr>
<td>‘W’</td>
<td>left</td>
</tr>
</tbody>
</table>

```python
set_aspect(aspect=False)
```

**Parameters**

- **aspect**: bool

```python
set_horizontal(h)
```

**Parameters**

- **h**: list of `axes_size`
  
  sizes for horizontal division

```python
set_locator(_locator)
```

```python
set_position(pos)
```

**Parameters**

- **pos**: tuple of 4 floats

  position of the rectangle that will be divided

```python
set_vertical(v)
```

**Parameters**

- **v**: list of `axes_size`

  sizes for vertical division

```python
class mpl_toolkits.axes_grid.axes_divider.AxesLocator(axes_divider, nx, ny, nx1=None, ny1=None)
```

A simple callable object, initialized with AxesDivider class, returns the position and size of the given cell.

**Parameters**

- **axes_divider**: AxesDivider

  - **nx, nx1**: int

    Integers specifying the column-position of the cell. When `nx1` is None, a single `nx`-th column is specified. Otherwise location of columns spanning between `nx` to `nx1` (but excluding `nx1`-th column) is specified.

  - **ny, ny1**: int

    Same as `nx` and `nx1`, but for row positions.
get_subplotspec()

class mpl_toolkits.axes_grid.axes_divider.SubplotDivider(fig, *args, **kwargs)
The Divider class whose rectangle area is specified as a subplot geometry.

Parameters

fig : matplotlib.figure.Figure

args : tuple (numRows, numCols, plotNum)

The array of subplots in the figure has dimensions numRows, numCols, and
plotNum is the number of the subplot being created. plotNum starts at 1 in the
upper left corner and increases to the right.

If numRows <= numCols <= plotNum < 10, args can be the decimal integer
numRows * 100 + numCols * 10 + plotNum.

cancel_geometry(numrows, numcols, num)

cancel subplot geometry, e.g., from 1,1,1 to 2,2,3

get_subplotspec()

get the SubplotSpec instance

set_subplotspec(subplotspec)

set the SubplotSpec instance

update_params()

update the subplot position from fig.subplotpars

class mpl_toolkits.axes_grid.axes_divider.AxesDivider(axes, xref=None, yref=None)

Divider based on the pre-existing axes.

Parameters

axes : Axes

xref

yref

append_axes(position, size, pad=None, add_to_figure=True, **kwargs)

create an axes at the given position with the same height (or width) of the main axes.

Parameters

position ['left','right','bottom','top']

size and pad should be axes_grid.axes_size compatible.

new_horizontal(size, pad=None, pack_start=False, **kwargs)

Add a new axes on the right (or left) side of the main axes.

Parameters

size : axes_size or float or string

A width of the axes. If float or string is given, from_any function is used to
create the size, with ref_size set to AxesX instance of the current axes.
pad : *axes_size* or float or string
    Pad between the axes. It takes same argument as *size*.

**pack_start** : bool
    If False, the new axes is appended at the end of the list, i.e., it became the
    right-most axes. If True, it is inserted at the start of the list, and becomes the
    left-most axes.

**kwargs**
    All extra keywords arguments are passed to the created axes. If *axes_class* is
    given, the new axes will be created as an instance of the given class. Other-
    wise, the same class of the main axes will be used.

*new_vertical* (*size*, *pad*=None, *pack_start*=False, **kwargs)
    Add a new axes on the top (or bottom) side of the main axes.

**Parameters**

**size** : *axes_size* or float or string
    A height of the axes. If float or string is given, *from_any* function is used to
    create the size, with *ref_size* set to *AxesX* instance of the current axes.

**pad** : *axes_size* or float or string
    Pad between the axes. It takes same argument as *size*.

**pack_start** : bool
    If False, the new axes is appended at the end of the list, i.e., it became the
    right-most axes. If True, it is inserted at the start of the list, and becomes the
    left-most axes.

**kwargs**
    All extra keywords arguments are passed to the created axes. If *axes_class* is
    given, the new axes will be created as an instance of the given class. Other-
    wise, the same class of the main axes will be used.

### 67.3 mpl_toolkits.axes_grid.axes_grid

**class** mpl_toolkits.axes_grid.axes_grid.Grid(fig, rect, nrows, ncols, ngrids=None, direction='row', axes_pad=0.02, add_all=True, share_all=False, share_x=True, share_y=True, label_mode='L', axes_class=None)

Build an Grid instance with a grid nrows*ncols *Axes* in *Figure* fig with *rect*=[left, bottom, width, height] (in *Figure* coordinates) or the subplot position code (e.g., “121”).

Optional keyword arguments:
Matplotlib, Release 2.0.0

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>direction</td>
<td>&quot;row&quot;</td>
<td>[ &quot;row&quot;</td>
</tr>
<tr>
<td>axes_pad</td>
<td>0.02</td>

<td>a type object which must be a subclass of Axes</td>
</tr>
</tbody>
</table>

```python
class mpl_toolkits.axes_grid.axes_grid.ImageGrid(fig, rect, nrows_ncols, ngrids=None, direction='row', axes_pad=0.02, add_all=True, share_all=False, aspect=True, label_mode='L', cbar_mode=None, cbar_location='right', cbar_pad=None, cbar_size='5%', cbar_set_cax=True, axes_class=None)
```

Build an ImageGrid instance with a grid nrows*ncols Axes in Figure fig with rect=[left, bottom, width, height] (in Figure coordinates) or the subplot position code (e.g., “121”).

Optional keyword arguments:

<table>
<thead>
<tr>

<td>a type object which must be a subclass of axes_grid’s subclass of Axes</td>
</tr>
</tbody>
</table>

`cbar_set_cax` [if True, each axes in the grid has a cax] attribute that is bind to associated cbar_axes.
67.4 *mpl_toolkits.axes_grid.axis_artist*

class *mpl_toolkits.axes_grid.axis_artist.AxisArtist*(axes, helper, offset=None,

\[\text{axis direction} = 'bottom', **kw\]

An artist which draws axis (a line along which the n-th axes coord is constant) line, ticks, ticklabels, and axis label.

axes : axes
helper : an AxisArtistHelper instance.

**LABELPAD**

**ZORDER** = 2.5

**draw**(*artist, renderer, *args, **kwargs*)

Draw the axis lines, tick lines and labels

**get_axisline_style**()

return the current axisline style.

**get_helper**()

Return axis artist helper instance.

**get_tightbbox**(renderer)

**get_transform**()

**invert_ticklabel_direction**()

**set_axis_direction**(*axis_direction*)

Adjust the direction, text angle, text alignment of ticklabels, labels following the matplotlib convention for the rectangle axes.

The *axis_direction* must be one of [left, right, bottom, top].

<table>
<thead>
<tr>
<th>property</th>
<th>left</th>
<th>bottom</th>
<th>right</th>
<th>top</th>
</tr>
</thead>
<tbody>
<tr>
<td>ticklabels location</td>
<td>“-”</td>
<td>“+”</td>
<td>“+”</td>
<td>“-”</td>
</tr>
<tr>
<td>axislabel location</td>
<td>“-”</td>
<td>“+”</td>
<td>“+”</td>
<td>“-”</td>
</tr>
<tr>
<td>ticklabels angle</td>
<td>90</td>
<td>0</td>
<td>-90</td>
<td>180</td>
</tr>
<tr>
<td>ticklabel va</td>
<td>center</td>
<td>baseline</td>
<td>center</td>
<td>baseline</td>
</tr>
<tr>
<td>ticklabel ha</td>
<td>right</td>
<td>center</td>
<td>right</td>
<td>center</td>
</tr>
<tr>
<td>axislabel angle</td>
<td>180</td>
<td>0</td>
<td>0</td>
<td>180</td>
</tr>
<tr>
<td>axislabel va</td>
<td>center</td>
<td>top</td>
<td>center</td>
<td>bottom</td>
</tr>
<tr>
<td>axislabel ha</td>
<td>right</td>
<td>center</td>
<td>right</td>
<td>center</td>
</tr>
</tbody>
</table>

Note that the direction “+” and “-” are relative to the direction of the increasing coordinate. Also, the text angles are actually relative to (90 + angle of the direction to the ticklabel), which gives 0 for bottom axis.
**set_axislabel_direction**(*label_direction*)
Adjust the direction of the axislabel.

Accepts: [“+” | “-” ]

Note that the label_direction ‘+’ and ‘-’ are relative to the direction of the increasing coordinate.

**set_axisline_style**(*axisline_style=None, **kw*)
Set the axisline style.

**axisline_style** can be a string with axisline style name with optional comma-separated attributes. Alternatively, the attrs can be provided as keywords.

```
set_arrowstyle("->", size=1.5")
set_arrowstyle("<->", size=1.5)
```

Old attrs simply are forgotten.
Without argument (or with arrowstyle=none), return available styles as a list of strings.

**set_label**(*s*)

**set_ticklabel_direction**(*tick_direction*)
Adjust the direction of the ticklabel.

Accepts: [“+” | “-” ]

Note that the label_direction ‘+’ and ‘-’ are relative to the direction of the increasing coordinate.

**toggle**(*all=None, ticks=None, ticklabels=None, label=None*)
Toggle visibility of ticks, ticklabels, and (axis) label. To turn all off,

```
axis.toggle(all=False)
```

To turn all off but ticks on

```
axis.toggle(all=False, ticks=True)
```

To turn all on but (axis) label off

```
axis.toggle(all=True, label=False))
```

class mpl_toolkits.axes_grid.axis_artist.Ticks(*ticksize, tick_out=False, **kwargs*)
Ticks are derived from Line2D, and note that ticks themselves are markers. Thus, you should use set_mec, set_mew, etc.
To change the tick size (length), you need to use set_ticksize. To change the direction of the ticks (ticks are in opposite direction of ticklabels by default), use set_tick_out(False).

**get_tick_out**()
Return True if the tick will be rotated by 180 degree.

**get_ticksize**()
Return length of the ticks in points.

**set_tick_out**(b)
set True if tick need to be rotated by 180 degree.
**set_ticksize**(*ticksize*)
set length of the ticks in points.

class **mpl_toolkits.axes_grid.axis_artist.AxisLabel**(*kl, **kwargs*)
Axis Label. Derived from Text. The position of the text is updated in the fly, so changing text position has no effect. Otherwise, the properties can be changed as a normal Text.

To change the pad between ticklabels and axis label, use **set_pad**.

**get_pad**()
return pad in points. See **set_pad** for more details.

**set_axis_direction**(*d*)
Adjust the text angle and text alignment of axis label according to the matplotlib convention.

<table>
<thead>
<tr>
<th>property</th>
<th>left</th>
<th>bottom</th>
<th>right</th>
<th>top</th>
</tr>
</thead>
<tbody>
<tr>
<td>axislabel angle</td>
<td>180</td>
<td>0</td>
<td>0</td>
<td>180</td>
</tr>
<tr>
<td>axislabel va</td>
<td>center</td>
<td>top</td>
<td>center</td>
<td>bottom</td>
</tr>
<tr>
<td>axislabel ha</td>
<td>right</td>
<td>center</td>
<td>right</td>
<td>center</td>
</tr>
</tbody>
</table>

Note that the text angles are actually relative to (90 + angle of the direction to the ticklabel), which gives 0 for bottom axis.

**set_pad**(*pad*)
Set the pad in points. Note that the actual pad will be the sum of the internal pad and the external pad (that are set automatically by the AxisArtist), and it only set the internal pad

class **mpl_toolkits.axes_grid.axis_artist.TickLabels**(**kwargs**)
Tick Labels. While derived from Text, this single artist draws all ticklabels. As in AxisLabel, the position of the text is updated in the fly, so changing text position has no effect. Otherwise, the properties can be changed as a normal Text. Unlike the ticklabels of the mainline matplotlib, properties of single ticklabel alone cannot modified.

To change the pad between ticks and ticklabels, use **set_pad**.

**get_texts_widths_heights_descents**(*renderer*)
return a list of width, height, descent for ticklabels.

**set_axis_direction**(*label_direction*)
Adjust the text angle and text alignment of ticklabels according to the matplotlib convention.

The **label_direction** must be one of [left, right, bottom, top].

<table>
<thead>
<tr>
<th>property</th>
<th>left</th>
<th>bottom</th>
<th>right</th>
<th>top</th>
</tr>
</thead>
<tbody>
<tr>
<td>ticklabels angle</td>
<td>90</td>
<td>0</td>
<td>-90</td>
<td>180</td>
</tr>
<tr>
<td>ticklabel va</td>
<td>center</td>
<td>baseline</td>
<td>center</td>
<td>baseline</td>
</tr>
<tr>
<td>ticklabel ha</td>
<td>right</td>
<td>center</td>
<td>right</td>
<td>center</td>
</tr>
</tbody>
</table>

Note that the text angles are actually relative to (90 + angle of the direction to the ticklabel), which gives 0 for bottom axis.
68.1 mpl_toolkits.axes_grid1.anchored_artists

class mpl_toolkits.axes_grid1.anchored_artists.AnchoredAuxTransformBox(transform, loc, pad=0.4, borderpad=0.5, prop=None, frameon=True, **kwargs)

Bases: matplotlib.offsetbox.AnchoredOffsetbox

An anchored container with transformed coordinates.

Artists added to the drawing_area are scaled according to the coordinates of the transformation used. The dimensions of this artist will scale to contain the artists added.

Parameters

- **transform**: matplotlib.transforms.Transform
  
The transformation object for the coordinate system in use, i.e., matplotlib.axes.Axes.transData.

- **loc**: int
  
Location of this artist. Valid location codes are:

- 'upper right' : 1,
- 'upper left'  : 2,
- 'lower left'  : 3,
- 'lower right' : 4,
- 'right'       : 5,
- 'center left' : 6,
- 'center right': 7,
- 'lower center': 8,
'upper center' : 9,
'center' : 10

pad : int or float, optional
Padding around the child objects, in fraction of the font size. Defaults to 0.4.

borderpad : int or float, optional
Border padding, in fraction of the font size. Defaults to 0.5.

prop : matplotlib.font_manager.FontProperties, optional
Font property used as a reference for paddings.

frameon : bool, optional
If True, draw a box around this artists. Defaults to True.

**kwargs :
Keyworded arguments to pass to matplotlib.offsetbox.AnchoredOffsetbox.

Examples

To display an ellipse in the upper left, with a width of 0.1 and height of 0.4 in data coordinates:

```python
>>> box = AnchoredAuxTransformBox(ax.transData, loc=2)
>>> el = Ellipse((0,0), width=0.1, height=0.4, angle=30)
>>> box.drawing_area.add_artist(el)
>>> ax.add_artist(box)
```

Attributes

| drawing_area | (matplotlib.offsetbox.AuxTransformBox) A container for artists to display. |

class mpl_toolkits.axes_grid1.anchored_artists.AnchoredDrawingArea

An anchored container with a fixed size and fillable DrawingArea.

Artists added to the drawing_area will have their coordinates interpreted as pixels. Any transformations set on the artists will be overridden.
Parameters

- **width, height**: int or float
  - width and height of the container, in pixels.

- **xdescent, ydescent**: int or float
  - descent of the container in the x- and y- direction, in pixels.

- **loc**: int
  - Location of this artist. Valid location codes are:
    ```
    {'upper right': 1,  
    'upper left': 2,  
    'lower left': 3,  
    'lower right': 4,  
    'right': 5,  
    'center left': 6,  
    'center right': 7,  
    'lower center': 8,  
    'upper center': 9,  
    'center': 10}
    ```

- **pad**: int or float, optional
  - Padding around the child objects, in fraction of the font size. Defaults to 0.4.

- **borderpad**: int or float, optional
  - Border padding, in fraction of the font size. Defaults to 0.5.

- **prop**: matplotlib.font_manager.FontProperties, optional
  - Font property used as a reference for paddings.

- **frameon**: bool, optional
  - If True, draw a box around this artists. Defaults to True.

- ****kwargs**:
  - Keyworded arguments to pass to matplotlib.offsetbox.AnchoredOffsetbox.

**Examples**

To display blue and red circles of different sizes in the upper right of an axes `ax`:

```python
>>> ada = AnchoredDrawingArea(20, 20, 0, 0, loc=1, frameon=False)  
>>> ada.drawing_area.add_artist(Circle((10, 10), 10, fc="b"))  
>>> ada.drawing_area.add_artist(Circle((30, 10), 5, fc="r"))  
>>> ax.add_artist(ada)
```
Attributes

drawing_area (matplotlib.offsetbox.DrawingArea) A container for artists to display.

class mpl_toolkits.axes_grid1.anchored_artists.AnchoredEllipse (transform, width, height, angle, loc, pad=0.1, borderpad=0.1, prop=None, frameon=True, **kwargs)

Bases: matplotlib.offsetbox.AnchoredOffsetbox

Draw an anchored ellipse of a given size.

**Parameters**

**transform**: matplotlib.transforms.Transform

The transformation object for the coordinate system in use, i.e., matplotlib.axes.Axes.transData.

**width, height**: int or float

Width and height of the ellipse, given in coordinates of transform.

**angle**: int or float

Rotation of the ellipse, in degrees, anti-clockwise.

**loc**: int

Location of this size bar. Valid location codes are:

<table>
<thead>
<tr>
<th>Location Code</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'upper right'</td>
<td>1</td>
</tr>
<tr>
<td>'upper left'</td>
<td>2</td>
</tr>
<tr>
<td>'lower left'</td>
<td>3</td>
</tr>
<tr>
<td>'lower right'</td>
<td>4</td>
</tr>
<tr>
<td>'right'</td>
<td>5</td>
</tr>
<tr>
<td>'center left'</td>
<td>6</td>
</tr>
<tr>
<td>'center right'</td>
<td>7</td>
</tr>
<tr>
<td>'lower center'</td>
<td>8</td>
</tr>
<tr>
<td>'upper center'</td>
<td>9</td>
</tr>
<tr>
<td>'center'</td>
<td>10</td>
</tr>
</tbody>
</table>

**pad**: int or float, optional

Padding around the ellipse, in fraction of the font size. Defaults to 0.1.

**borderpad**: int or float, optional

Border padding, in fraction of the font size. Defaults to 0.1.

**frameon**: bool, optional

If True, draw a box around the ellipse. Defaults to True.

**prop**: matplotlib.font_manager.FontProperties, optional
Font property used as a reference for paddings.

**kwargs :

Keyworded arguments to pass to matplotlib.offsetbox.AnchoredOffsetbox.

Attributes

| ellipse | (matplotlib.patches.Ellipse) | Ellipse patch drawn. |

class mpl_toolkits.axes_grid1.anchored_artists.AnchoredSizeBar(transform, size, label, loc, pad=0.1, borderpad=0.1, sep=2, frameon=True, size_vertical=0, color='black', label_top=False, fontproperties=None, **kwargs) |

Bases: matplotlib.offsetbox.AnchoredOffsetbox

Draw a horizontal scale bar with a center-aligned label underneath.

**Parameters**

**transform** : matplotlib.transforms.Transform

The transformation object for the coordinate system in use, i.e., matplotlib.axes.Axes.transData.

**size** : int or float

Horizontal length of the size bar, given in coordinates of transform.

**label** : str

Label to display.

**loc** : int

Location of this size bar. Valid location codes are:

| 'upper right'   : 1,                  |
| 'upper left'    : 2,                  |
| 'lower left'    : 3,                  |
| 'lower right'   : 4,                  |
| 'right'         : 5,                  |
| 'center left'   : 6,                  |
| 'center right'  : 7,                  |
| 'lower center'  : 8,                  |
| 'upper center'  : 9,                  |
| 'center'        : 10                  |

**pad** : int or float, optional
Padding around the label and size bar, in fraction of the font size. Defaults to 0.1.

**borderpad**: int or float, optional

Border padding, in fraction of the font size. Defaults to 0.1.

**sep**: int or float, optional

Separation between the label and the size bar, in points. Defaults to 2.

**frameon**: bool, optional

If True, draw a box around the horizontal bar and label. Defaults to True.

**size_vertical**: int or float, optional

Vertical length of the size bar, given in coordinates of *transform*. Defaults to 0.

**color**: str, optional

Color for the size bar and label. Defaults to black.

**label_top**: bool, optional

If True, the label will be over the size bar. Defaults to False.

**fontproperties**: *matplotlib.font_manager.FontProperties*, optional

Font properties for the label text.

**kwargs**:

Keyworded arguments to pass to *matplotlib.offsetbox.AnchoredOffsetbox*.

**Notes**

If *prop* is passed as a keyworded argument, but *fontproperties* is not, then *prop* is be assumed to be the intended *fontproperties*. Using both *prop* and *fontproperties* is not supported.

**Examples**

```python
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from mpl_toolkits.axes_grid1.anchored_artists import AnchoredSizeBar
>>> fig, ax = plt.subplots()
>>> ax.imshow(np.random.random((10,10)))
>>> bar = AnchoredSizeBar(ax.transData, 3, '3 data units', 4)
>>> ax.add_artist(bar)
>>> fig.show()
```

Using all the optional parameters
>>> import matplotlib.font_manager as fm
>>> fontprops = fm.FontProperties(size=14, family='monospace')
>>> bar = AnchoredSizeBar(ax.transData, 3, '3 units', 4, pad=0.5, sep=5,
                         borderpad=0.5, frameon=False, size_vertical=0.5, color='white',
                         fontproperties=fontprops)

Attributes

| size_bar  | (matplotlib.offsetbox.AuxTransformBox) Container for the size bar. |
| txt_label | (matplotlib.offsetbox.TextArea) Container for the label of the size bar. |

### 68.2 mpl_toolkits.axes_grid1.inset_locator

A collection of functions and objects for creating or placing inset axes.

class mpl_toolkits.axes_grid1.inset_locator.AnchoredLocatorBase(bbox_to_anchor, offsetbox, loc, borderpad=0.5, bbox_transform=None)

Bases: matplotlib.offsetbox.AnchoredOffsetbox
draw(renderer)

class mpl_toolkits.axes_grid1.inset_locator.AnchoredSizeLocator(bbox_to_anchor, x_size, y_size, loc, borderpad=0.5, bbox_transform=None)

Bases: mpl_toolkits.axes_grid1.inset_locator.AnchoredLocatorBase
get_extent(renderer)

class mpl_toolkits.axes_grid1.inset_locator.AnchoredZoomLocator(parent_axes, zoom, loc, borderpad=0.5, bbox_to_anchor=None, bbox_transform=None)

Bases: mpl_toolkits.axes_grid1.inset_locator.AnchoredLocatorBase
get_extent(renderer)

class mpl_toolkits.axes_grid1.inset_locator.BboxConnector(bbox1, bbox2, loc1, loc2=None, **kwargs)

Bases: matplotlib.patches.Patch

Connect two bboxes with a straight line.

Parameters bbox1, bbox2 : matplotlib.transforms.Bbox
Bounding boxes to connect.

**loc1** : {1, 2, 3, 4}

Corner of *bbox1* to draw the line. Valid values are:

```
'upper right' : 1,  
'upper left' : 2,  
'lower left' : 3,  
'lower right' : 4
```

**loc2** : {1, 2, 3, 4}, optional

Corner of *bbox2* to draw the line. If None, defaults to *loc1*. Valid values are:

```
'upper right' : 1,  
'upper left' : 2,  
'lower left' : 3,  
'lower right' : 4
```

**kwargs

Patch properties for the line drawn. Valid arguments include:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agg_filter</td>
<td>unknown</td>
</tr>
<tr>
<td>alpha</td>
<td>float or None</td>

</tbody>
</table>

**static connect_bbox** *(bbox1, bbox2, loc1, loc2=None)*

Helper function to obtain a Path from one bbox to another.

**Parameters**
- **bbox1, bbox2**: `matplotlib.transforms.Bbox`
  Bounding boxes to connect.
- **loc1**: `{1, 2, 3, 4}`
  Corner of `bbox1` to use. Valid values are:
  ```
  'upper right' : 1,
  'upper left'  : 2,
  'lower left'  : 3,
  'lower right' : 4
  ```
- **loc2**: `{1, 2, 3, 4}`, optional
  Corner of `bbox2` to use. If None, defaults to `loc1`. Valid values are:
  ```
  'upper right' : 1,
  'upper left'  : 2,
  'lower left'  : 3,
  'lower right' : 4
  ```

**Returns** `matplotlib.path.Path`

A line segment from the `loc1` corner of `bbox1` to the `loc2` corner of `bbox2`.

**static get_bbox_edge_pos** *(bbox, loc)*

Helper function to obtain the location of a corner of a bbox

**Parameters**
- **bbox**: `matplotlib.transforms.Bbox`
  Corner of `bbox` to use.
  ```
  'upper right' : 1,
  'upper left'  : 2,
  'lower left'  : 3,
  'lower right' : 4
  ```

**Returns** `x, y : float`

Coordinates of the corner specified by `loc`. 

68.2. `mpl_toolkits.axes_grid1.inset_locator`
**get_path()**

Return the path of this patch.

```python
class mpl_toolkits.axes_grid1.inset_locator.BboxConnectorPatch(bbox1, bbox2, loc1a, loc2a, loc1b, loc2b, **kwargs)
```

Bases: `mpl_toolkits.axes_grid1.inset_locator.BboxConnector`

Connect two bboxes with a quadrilateral.

The quadrilateral is specified by two lines that start and end at corners of the bboxes. The four sides of the quadrilateral are defined by the two lines given, the line between the two corners specified in `bbox1` and the line between the two corners specified in `bbox2`.

**Parameters**

- `bbox1`, `bbox2`: `matplotlib.transforms.Bbox`
  
  Bounding boxes to connect.

- `loc1a`, `loc2a`: `{1, 2, 3, 4}`
  
  Corners of `bbox1` and `bbox2` to draw the first line. Valid values are:

  ```
  'upper right' : 1,
  'upper left' : 2,
  'lower left' : 3,
  'lower right' : 4
  ```

- `loc1b`, `loc2b`: `{1, 2, 3, 4}`
  
  Corners of `bbox1` and `bbox2` to draw the second line. Valid values are:

  ```
  'upper right' : 1,
  'upper left' : 2,
  'lower left' : 3,
  'lower right' : 4
  ```

- `**kwargs`
  
  Patch properties for the line drawn:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agg_filter</td>
<td>unknown</td>
</tr>
<tr>
<td>alpha</td>

**get_path()**

Return the path of this patch.

**class mpl_toolkits.axes_grid1.inset_locator.BboxPatch(bbox, **kwargs)**

Bases: `matplotlib.patches.Patch`

Patch showing the shape bounded by a Bbox.

**Parameters**

- **bbox**: `matplotlib.transforms.Bbox`

  Bbox to use for the extents of this patch.

**kwargs**

Patch properties. Valid arguments include:

<table>
<thead>

`get_path()`
Return the path of this patch

```python
class mpl_toolkits.axes_grid1.inset_locator.InsetPosition(parent, lbwh)
    Bases: object

    An object for positioning an inset axes.

    This is created by specifying the normalized coordinates in the axes, instead of the figure.

    Parameters

    parent: `matplotlib.axes.Axes`

    Axes to use for normalizing coordinates.

    `lbwh`: iterable of four floats

    The left edge, bottom edge, width, and height of the inset axes, in units of the normalized coordinate of the parent axes.

    See also:

    `matplotlib.axes.Axes.set_axes_locator()`
```
Examples

The following bounds the inset axes to a box with 20% of the parent axes’s height and 40% of the width. The size of the axes specified ([0, 0, 1, 1]) ensures that the axes completely fills the bounding box:

```python
>>> parent_axes = plt.gca()
>>> ax_ins = plt.axes([0, 0, 1, 1])
>>> ip = InsetPosition(ax, [0.5, 0.1, 0.4, 0.2])
>>> ax_ins.set_axes_locator(ip)
```

Create an inset axes with a given width and height.

Both sizes used can be specified either in inches or percentage of the parent axes.

**Parameters**

- **parent_axes**: `matplotlib.axes.Axes`
  
  Axes to place the inset axes.

- **width, height**: float or str
  
  Size of the inset axes to create.

- **loc**: int or string, optional, default to 1
  
  Location to place the inset axes. The valid locations are:

  ```
  'upper right' : 1,
  'upper left' : 2,
  'lower left' : 3,
  'lower right' : 4,
  'right' : 5,
  'center left' : 6,
  'center right' : 7,
  'lower center' : 8,
  'upper center' : 9,
  'center' : 10
  ```

- **bbox_to_anchor**: tuple or `matplotlib.transforms.BboxBase`, optional
  
  Bbox that the inset axes will be anchored. Can be a tuple of [left, bottom, width, height], or a tuple of [left, bottom].

- **bbox_transform**: `matplotlib.transforms.Transform`, optional
  
  Transformation for the bbox. if None, `parent_axes.transAxes` is used.

- **axes_class**: `matplotlib.axes.Axes` type, optional
  
  If specified, the inset axes created with be created with this class’s constructor.
axes_kwargs : dict, optional

Keyworded arguments to pass to the constructor of the inset axes. Valid arguments include:

<table>

</tbody>
</table>

Padding between inset axes and the bbox_to_anchor. Defaults to 0.5.

Returns inset_axes : axes_class

Inset axes object created.

mpl_toolkits.axes_grid1.inset_locator.mark_inset(parent_axes, inset_axes, loc1, loc2, **kwargs)

Draw a box to mark the location of an area represented by an inset axes.

This function draws a box in parent_axes at the bounding box of inset_axes, and shows a connection with the inset axes by drawing lines at the corners, giving a “zoomed in” effect.

Parameters parent_axes : matplotlib.axes.Axes

Axes which contains the area of the inset axes.

inset_axes : matplotlib.axes.Axes

The inset axes.

loc1, loc2 : {1, 2, 3, 4}

Corners to use for connecting the inset axes and the area in the parent axes.

**kwargs

Patch properties for the lines and box drawn:

</tbody>
</table>

Returns **pp**: `matplotlib.patches.Patch`

The patch drawn to represent the area of the inset axes.

**p1, p2**: `matplotlib.patches.Patch`

The patches connecting two corners of the inset axes and its area.

```python
mpl_toolkits.axes_grid1.inset_locator.zoomed_inset_axes(parent_axes, zoom, loc=1, bbox_to_anchor=None, bbox_transform=None, axes_class=None, axes kwARGS=None, borderpad=0.5)
```

Create an anchored inset axes by scaling a parent axes.

**Parameters parent_axes**: `matplotlib.axes.Axes`

Axes to place the inset axes.

**zoom**: float

Scaling factor of the data axes. `zoom > 1` will enlargen the coordinates (i.e., “zoomed in”), while `zoom < 1` will shrink the coordinates (i.e., “zoomed out”).
loc : int or string, optional, default to 1

Location to place the inset axes. The valid locations are:

```
'upper right' : 1,
'upper left' : 2,
'lower left' : 3,
'lower right' : 4,
'right' : 5,
'center left' : 6,
'center right' : 7,
'lower center' : 8,
'upper center' : 9,
'center' : 10
```

bbox_to_anchor : tuple or `matplotlib.transforms.BboxBase`, optional

Bbox that the inset axes will be anchored. Can be a tuple of \([\text{left}, \text{bottom}, \text{width}, \text{height}]\), or a tuple of \([\text{left}, \text{bottom}]\).

bbox_transform : `matplotlib.transforms.Transform`, optional

Transformation for the bbox. If None, `parent_axes.transAxes` is used.

axes_class : `matplotlib.axes.Axes` type, optional

If specified, the inset axes created with be created with this class’s constructor.

axes_kwargs : dict, optional

Keyworded arguments to pass to the constructor of the inset axes. Valid arguments include:

<table>

**borderpad** : float, optional

Padding between inset axes and the bbox_to_anchor. Defaults to 0.5.

**Returns inset_axes** : axes_class

Inset axes object created.
Part V

mplot3d
MATPLOTLIB MPLT3D TOOLKIT

The mplot3d toolkit adds simple 3D plotting capabilities to matplotlib by supplying an axes object that can create a 2D projection of a 3D scene. The resulting graph will have the same look and feel as regular 2D plots.

The interactive backends also provide the ability to rotate and zoom the 3D scene. One can rotate the 3D scene by simply clicking-and-dragging the scene. Zooming is done by right-clicking the scene and dragging the mouse up and down. Note that one does not use the zoom button like one would use for regular 2D plots.

69.1.1 Getting started

An Axes3D object is created just like any other axes using the projection='3d' keyword. Create a new matplotlib.figure.Figure and add a new axes to it of type Axes3D:

```python
import matplotlib.pyplot as plt
from mpl_toolkits.mplot3d import Axes3D
fig = plt.figure()
ax = fig.add_subplot(111, projection='3d')
```

New in version 1.0.0: This approach is the preferred method of creating a 3D axes.

**Note:** Prior to version 1.0.0, the method of creating a 3D axes was different. For those using older versions of matplotlib, change `ax = fig.add_subplot(111, projection='3d')` to `ax = Axes3D(fig)`. 
69.1.2 Line plots

**Axes3D.plot** *(xs, ys, *args, **kwargs)*

Plot 2D or 3D data.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xs, ys</td>
<td>x, y coordinates of vertices</td>
</tr>
<tr>
<td>zs</td>
<td>z value(s), either one for all points or one for each point.</td>
</tr>
<tr>
<td>zdir</td>
<td>Which direction to use as z (‘x’, ‘y’ or ‘z’) when plotting a 2D set.</td>
</tr>
</tbody>
</table>

Other arguments are passed on to `plot()`

![parametric curve](image)

69.1.3 Scatter plots

**Axes3D.scatter** *(xx, ys, zs=0, zdir='z', s=20, c=None, depthshade=True, *args, **kwargs)*

Create a scatter plot.
### Argument Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xs, ys</td>
<td>Positions of data points.</td>
</tr>
<tr>
<td>zs</td>
<td>Either an array of the same length as xs and ys or a single value to place all points in the same plane. Default is 0.</td>
</tr>
<tr>
<td>zdir</td>
<td>Which direction to use as z (‘x’, ‘y’ or ‘z’) when plotting a 2D set.</td>
</tr>
<tr>
<td>s</td>
<td>Size in points^2. It is a scalar or an array of the same length as x and y.</td>
</tr>
<tr>
<td>c</td>
<td>A color. c can be a single color format string, or a sequence of color specifications of length N, or a sequence of N numbers to be mapped to colors using the cmap and norm specified via kwargs (see below). Note that c should not be a single numeric RGB or RGBA sequence because that is indistinguishable from an array of values to be colormapped. c can be a 2-D array in which the rows are RGB or RGBA, however, including the case of a single row to specify the same color for all points.</td>
</tr>
</tbody>
</table>

**depthshade** Whether or not to shade the scatter markers to give the appearance of depth. Default is True.

Keyword arguments are passed on to `scatter()`.

Returns a `Patch3DCollection`
### 69.1.4 Wireframe plots

**Axes3D.plot_wireframe**(*X, Y, Z, *args, **kwargs*)

Plot a 3D wireframe.

The *rstride* and *cstride* kwargs set the stride used to sample the input data to generate the graph. If either is 0 the input data in not sampled along this direction producing a 3D line plot rather than a wireframe plot. The stride arguments are only used by default if in the ‘classic’ mode. They are now superseded by *rcount* and *ccount*. Will raise ValueError if both stride and count are used.

* The **rcount** and **ccount** kwargs supersedes **rstride** and **cstride** for default sampling method for wireframe plotting. These arguments will determine at most how many evenly spaced samples will be taken from the input data to generate the graph. This is the default sampling method unless using the ‘classic’ style. Will raise ValueError if both stride and count are specified. If either is zero, then the input data is not sampled along this direction, producing a 3D line plot rather than a wireframe plot. Added in v2.0.0.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>X, Y,</em></td>
<td>Data values as 2D arrays</td>
</tr>
<tr>
<td><em>Z</em></td>
<td></td>
</tr>
<tr>
<td><em>rstride</em></td>
<td>Array row stride (step size), defaults to 1</td>
</tr>
<tr>
<td><em>cstride</em></td>
<td>Array column stride (step size), defaults to 1</td>
</tr>
<tr>
<td><em>rcount</em></td>
<td>Use at most this many rows, defaults to 50</td>
</tr>
<tr>
<td><em>ccount</em></td>
<td>Use at most this many columns, defaults to 50</td>
</tr>
</tbody>
</table>

Keyword arguments are passed on to `LineCollection`.

Returns a `Line3DCollection`
69.1.5 Surface plots

Axes3D.plot_surface(X, Y, Z, *args, **kwargs)

Create a surface plot.

By default it will be colored in shades of a solid color, but it also supports color mapping by supplying the cmap argument.

The rstride and cstride kwargs set the stride used to sample the input data to generate the graph. If 1k by 1k arrays are passed in, the default values for the strides will result in a 100x100 grid being plotted. Defaults to 10. Raises a ValueError if both stride and count kwargs (see next section) are provided.

The rcount and ccount kwargs supersede rstride and cstride for default sampling method for surface plotting. These arguments will determine at most how many evenly spaced samples will be taken from the input data to generate the graph. This is the default sampling method unless using the ‘classic’ style. Will raise ValueError if both stride and count are specified. Added in v2.0.0.
<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X, Y, Z</td>
<td>Data values as 2D arrays</td>
</tr>
<tr>
<td>rstride</td>
<td>Array row stride (step size)</td>
</tr>
<tr>
<td>cstride</td>
<td>Array column stride (step size)</td>
</tr>
<tr>
<td>rcount</td>
<td>Use at most this many rows, defaults to 50</td>
</tr>
<tr>
<td>ccount</td>
<td>Use at most this many columns, defaults to 50</td>
</tr>
<tr>
<td>color</td>
<td>Color of the surface patches</td>
</tr>
<tr>
<td>cmap</td>
<td>A colormap for the surface patches.</td>
</tr>
<tr>
<td>facecolors</td>
<td>Face colors for the individual patches</td>
</tr>
<tr>
<td>norm</td>
<td>An instance of Normalize to map values to colors</td>
</tr>
<tr>
<td>vmin</td>
<td>Minimum value to map</td>
</tr>
<tr>
<td>vmax</td>
<td>Maximum value to map</td>
</tr>
<tr>
<td>shade</td>
<td>Whether to shade the facecolors</td>
</tr>
</tbody>
</table>

Other arguments are passed on to *Poly3DCollection*
Chapter 69. Matplotlib mplot3d toolkit
69.1.6 Tri-Surface plots

Axes3D.plot_trisurf(*args, **kwargs)

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X, Y, Z</td>
<td>Data values as 1D arrays</td>
</tr>
<tr>
<td>color</td>
<td>Color of the surface patches</td>
</tr>
<tr>
<td>cmap</td>
<td>A colormap for the surface patches.</td>
</tr>
<tr>
<td>norm</td>
<td>An instance of Normalize to map values to colors</td>
</tr>
<tr>
<td>vmin</td>
<td>Minimum value to map</td>
</tr>
<tr>
<td>vmax</td>
<td>Maximum value to map</td>
</tr>
<tr>
<td>shade</td>
<td>Whether to shade the facecolors</td>
</tr>
</tbody>
</table>

The (optional) triangulation can be specified in one of two ways; either:

```python
plot_trisurf(triangulation, ...)
```

where triangulation is a `Triangulation` object, or:

```python
plot_trisurf(X, Y, ...)
pplot_trisurf(X, Y, triangles, ...)
pplot_trisurf(X, Y, triangles=triangles, ...)
```

in which case a Triangulation object will be created. See `Triangulation` for a explanation of these.
possibilities.
The remaining arguments are:

```
plot_trisurf(..., Z)
```

where $Z$ is the array of values to contour, one per point in the triangulation.

Other arguments are passed on to *Poly3DCollection*

**Examples:**
New in version 1.2.0: This plotting function was added for the v1.2.0 release.
69.1.7 Contour plots

Axes3D.contour(X, Y, Z, *args, **kwargs)
Create a 3D contour plot.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X, Y, Z</td>
<td>Data values as numpy.arrays</td>
</tr>
<tr>
<td>extend3d</td>
<td>Whether to extend contour in 3D (default: False)</td>
</tr>
<tr>
<td>stride</td>
<td>Stride (step size) for extending contour</td>
</tr>
<tr>
<td>zdir</td>
<td>The direction to use: x, y or z (default)</td>
</tr>
<tr>
<td>offset</td>
<td>If specified plot a projection of the contour lines on this position in plane normal to zdir</td>
</tr>
</tbody>
</table>

The positional and other keyword arguments are passed on to `contour()`.

Returns a `contour`
69.1.8 Filled contour plots

Axes3D.contourf(X, Y, Z, *args, **kwargs)
Create a 3D contourf plot.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X, Y, Z</td>
<td>Data values as numpy.arrays</td>
</tr>
<tr>
<td>zdir</td>
<td>The direction to use: x, y or z (default)</td>
</tr>
<tr>
<td>offset</td>
<td>If specified plot a projection of the filled contour on this position in plane normal to zdir</td>
</tr>
</tbody>
</table>

The positional and keyword arguments are passed on to contourf()

Returns a contourf

Changed in version 1.1.0: The zdir and offset kwargs were added.
New in version 1.1.0: The feature demoed in the second contourf3d example was enabled as a result of a bugfix for version 1.1.0.

69.1.9 Polygon plots

```
Axes3D.add_collection3d(col, zs=0, zdir='z')
```

Add a 3D collection object to the plot.

2D collection types are converted to a 3D version by modifying the object and adding z coordinate information.

Supported are:

- PolyCollection
- LineCollection
- PatchCollection
69.1.10 Bar plots

Axes3D.bar(\(left, height, zs=0, zdir='z', *args, **kwargs\))
Add 2D bar(s).

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(left)</td>
<td>The x coordinates of the left sides of the bars.</td>
</tr>
<tr>
<td>(height)</td>
<td>The height of the bars.</td>
</tr>
<tr>
<td>(zs)</td>
<td>Z coordinate of bars, if one value is specified they will all be placed at the same z.</td>
</tr>
<tr>
<td>(zdir)</td>
<td>Which direction to use as z (‘x’, ‘y’ or ‘z’) when plotting a 2D set.</td>
</tr>
</tbody>
</table>

Keyword arguments are passed onto bar().

Returns a Patch3DCollection
69.1.11 Quiver

Axes3D.quiver(*args, **kwargs)

Plot a 3D field of arrows.

call signatures:

```
quiver(X, Y, Z, U, V, W, **kwargs)
```

Arguments:

- **X, Y, Z:** The x, y and z coordinates of the arrow locations (default is tail of arrow; see `pivot` kwarg)
- **U, V, W:** The x, y and z components of the arrow vectors

The arguments could be array-like or scalars, so long as they can be broadcast together. The arguments can also be masked arrays. If an element in any of argument is masked, then that corresponding quiver element will not be plotted.

Keyword arguments:

- **length:** [1.0 | float] The length of each quiver, default to 1.0, the unit is the same with the axes
**arrow_length_ratio:** [0.3 | float] The ratio of the arrow head with respect to the quiver, default to 0.3

**pivot:** [‘tail’ | ‘middle’ | ‘tip’] The part of the arrow that is at the grid point; the arrow rotates about this point, hence the name *pivot*. Default is ‘tail’

**normalize:** [False | True] When True, all of the arrows will be the same length. This defaults to False, where the arrows will be different lengths depending on the values of u,v,w.

Any additional keyword arguments are delegated to *LineCollection*
69.1.12 2D plots in 3D

69.1.13 Text

```
Axes3D.text(x, y, z, zdir=None, **kwargs)
```

Add text to the plot. kwargs will be passed on to Axes.text, except for the `zdir` keyword, which sets the direction to be used as the z direction.
69.1.14 Subplotting

Having multiple 3D plots in a single figure is the same as it is for 2D plots. Also, you can have both 2D and 3D plots in the same figure.

New in version 1.0.0: Subplotting 3D plots was added in v1.0.0. Earlier version can not do this.
Chapter 69. Matplotlib mplot3d toolkit
A tale of 2 subplots

69.2 mplot3d API
Contents

  - proj3d

69.2.1 axes3d

Note: Significant effort went into bringing axes3d to feature-parity with regular axes objects for version 1.1.0. However, more work remains. Please report any functions that do not behave as expected as a bug. In addition, help and patches would be greatly appreciated!

Module containing Axes3D, an object which can plot 3D objects on a 2D matplotlib figure.

class mpl_toolkits.mplot3d.axes3d.Axes3D(fig, rect=None, *args, **kwargs)
    Bases: matplotlib.axes._axes.Axes

    3D axes object.

    add_collection3d(col, zs=0, zdir='z')
    Add a 3D collection object to the plot.

    2D collection types are converted to a 3D version by modifying the object and adding z coordinate information.

    Supported are:

    • PolyCollection
    • LineCollection
    • PatchCollection

    add_contour_set(cset, extend3d=False, stride=5, zdir='z', offset=None)

    add_contourf_set(cset, zdir='z', offset=None)

    auto_scale_xyz(X, Y, Z=None, had_data=None)

    autoscale(enable=True, axis='both', tight=None)
    Convenience method for simple axis view autoscaling. See matplotlib.axes.Axes.autoscale() for full explanation. Note that this function behaves the same, but for all three axes. Therefore, ‘z’ can be passed for axis, and ‘both’ applies to all three axes.
New in version 1.1.0: This function was added, but not tested. Please report any bugs.

**autoscale_view(tight=None, scalex=True, scaley=True, scalez=True)**

Autoscale the view limits using the data limits. See `matplotlib.axes.Axes.autoscale_view()` for documentation. Note that this function applies to the 3D axes, and as such adds the `scalez` to the function arguments.

Changed in version 1.1.0: Function signature was changed to better match the 2D version. `tight` is now explicitly a kwarg and placed first.

Changed in version 1.2.1: This is now fully functional.

**bar(left, height, zs=0, zdir='z', *args, **kwargs)**

Add 2D bar(s).

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>left</td>
<td>The x coordinates of the left sides of the bars.</td>
</tr>
<tr>
<td>height</td>
<td>The height of the bars.</td>
</tr>
<tr>
<td>zs</td>
<td>Z coordinate of bars, if one value is specified they will all be placed at the same z.</td>
</tr>
<tr>
<td>zdir</td>
<td>Which direction to use as z (‘x’, ‘y’ or ‘z’) when plotting a 2D set.</td>
</tr>
</tbody>
</table>

Keyword arguments are passed onto `bar()`.

Returns a `Patch3DCollection`

**bar3d(x, y, z, dx, dy, dz, color=None, zsort='average', *args, **kwargs)**

Generate a 3D bar, or multiple bars.

When generating multiple bars, x, y, z have to be arrays. dx, dy, dz can be arrays or scalars.

`color` can be:

- A single color value, to color all bars the same color.
- An array of colors of length N bars, to color each bar independently.
- An array of colors of length 6, to color the faces of the bars similarly.
- An array of colors of length 6 * N bars, to color each face independently.

When coloring the faces of the boxes specifically, this is the order of the coloring:

1. -Z (bottom of box)
2. +Z (top of box)
3. -Y
4. +Y
5. -X
6. +X

Keyword arguments are passed onto `Poly3DCollection()`
can_pan()
Return True if this axes supports the pan/zoom button functionality.
3D axes objects do not use the pan/zoom button.

can_zoom()
Return True if this axes supports the zoom box button functionality.
3D axes objects do not use the zoom box button.

cla()
Clear axes

clabel(*args, **kwargs)
This function is currently not implemented for 3D axes. Returns None.

contour(X, Y, Z, *args, **kwargs)
Create a 3D contour plot.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X, Y, Z</td>
<td>Data values as numpy.arrays</td>
</tr>
<tr>
<td>extend3d</td>
<td>Whether to extend contour in 3D (default: False)</td>
</tr>
<tr>
<td>stride</td>
<td>Stride (step size) for extending contour</td>
</tr>
<tr>
<td>zdir</td>
<td>The direction to use: x, y or z (default)</td>
</tr>
<tr>
<td>offset</td>
<td>If specified plot a projection of the contour lines on this position in plane normal to zdir</td>
</tr>
</tbody>
</table>

The positional and other keyword arguments are passed on to contour()
Returns a contour

contour3D(X, Y, Z, *args, **kwargs)
Create a 3D contour plot.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X, Y, Z</td>
<td>Data values as numpy.arrays</td>
</tr>
<tr>
<td>extend3d</td>
<td>Whether to extend contour in 3D (default: False)</td>
</tr>
<tr>
<td>stride</td>
<td>Stride (step size) for extending contour</td>
</tr>
<tr>
<td>zdir</td>
<td>The direction to use: x, y or z (default)</td>
</tr>
<tr>
<td>offset</td>
<td>If specified plot a projection of the contour lines on this position in plane normal to zdir</td>
</tr>
</tbody>
</table>

The positional and other keyword arguments are passed on to contour()
Returns a contour

contourf(X, Y, Z, *args, **kwargs)
Create a 3D contourf plot.
<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X, Y, Z</td>
<td>Data values as numpy.arrays</td>
</tr>
<tr>
<td>zdir</td>
<td>The direction to use: x, y or z (default)</td>
</tr>
<tr>
<td>offset</td>
<td>If specified plot a projection of the filled contour on this position in plane normal to zdir</td>
</tr>
</tbody>
</table>

The positional and keyword arguments are passed on to `contourf()`.

Returns a `contourf`.

Changed in version 1.1.0: The `zdir` and `offset` kwargs were added.

```python
contourf3D(X, Y, Z, *args, **kwargs)
```

Create a 3D contourf plot.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X, Y, Z</td>
<td>Data values as numpy.arrays</td>
</tr>
<tr>
<td>zdir</td>
<td>The direction to use: x, y or z (default)</td>
</tr>
<tr>
<td>offset</td>
<td>If specified plot a projection of the filled contour on this position in plane normal to zdir</td>
</tr>
</tbody>
</table>

The positional and keyword arguments are passed on to `contourf()`.

Returns a `contourf`.

Changed in version 1.1.0: The `zdir` and `offset` kwargs were added.

```python
convert_zunits(z)
```

For artists in an axes, if the zaxis has units support, convert `z` using zaxis unit type

New in version 1.2.1.

```python
disable_mouse_rotation()
```

Disable mouse button callbacks.

```python
draw(renderer)
```

```python
format_coord(xd, yd)
```

Given the 2D view coordinates attempt to guess a 3D coordinate. Looks for the nearest edge to the point and then assumes that the point is at the same z location as the nearest point on the edge.

```python
format_zdata(z)
```

Return `z` string formatted. This function will use the `fmt_zdata` attribute if it is callable, else will fall back on the zaxis major formatter

```python
get_autoscale_on()
```

Get whether autoscaling is applied for all axes on plot commands

New in version 1.1.0: This function was added, but not tested. Please report any bugs.
get_autoscalez_on()
    Get whether autoscaling for the z-axis is applied on plot commands

    New in version 1.1.0: This function was added, but not tested. Please report any bugs.

get_axis_position()

get_axisbelow()
    Get whether axis below is true or not.

    For axes3d objects, this will always be True

    New in version 1.1.0: This function was added for completeness.

get_children()

get_frame_on()
    Get whether the 3D axes panels are drawn

    New in version 1.1.0.

get_proj()
    Create the projection matrix from the current viewing position.

    elev stores the elevation angle in the z plane
    azim stores the azimuth angle in the x,y plane
    dist is the distance of the eye viewing point from the object point.

get_w_lims()
    Get 3D world limits.

get_xlim()
    Get the x-axis range

    Returns xlims : tuple

    Returns the current x-axis limits as the tuple (left, right).

Notes

The x-axis may be inverted, in which case the left value will be greater than the right value.

Changed in version 1.1.0: This function now correctly refers to the 3D x-limits

get_xlim3d()
    Get the x-axis range

    Returns xlims : tuple

    Returns the current x-axis limits as the tuple (left, right).
Notes

The x-axis may be inverted, in which case the left value will be greater than the right value.

Changed in version 1.1.0: This function now correctly refers to the 3D x-limits

get_xlim()
Get the y-axis range

    Returns ylims : tuple

    Returns the current y-axis limits as the tuple (bottom, top).

Notes

The y-axis may be inverted, in which case the bottom value will be greater than the top value.

Changed in version 1.1.0: This function now correctly refers to the 3D y-limits.

get_ylim3d()
Get the y-axis range

    Returns ylims : tuple

    Returns the current y-axis limits as the tuple (bottom, top).

Notes

The y-axis may be inverted, in which case the bottom value will be greater than the top value.

Changed in version 1.1.0: This function now correctly refers to the 3D y-limits.

get_zbound()
Returns the z-axis numerical bounds where:

    lowerBound < upperBound

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

get_zlabel()
Get the z-label text string.

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

get_zlim()
Get 3D z limits.

get_zlim3d()
Get 3D z limits.

get_zmajorticklabels()
Get the ztick labels as a list of Text instances

New in version 1.1.0.
get_zminorticklabels()
Get the ztick labels as a list of Text instances

Note: Minor ticks are not supported. This function was added only for completeness.

New in version 1.1.0.

get_zscale()

get_zticklabels(minor=False)
Get ztick labels as a list of Text instances. See matplotlib.axes.Axes.get_yticklabels() for more details.

Note: Minor ticks are not supported.

New in version 1.1.0.

get_zticklines()
Get ztick lines as a list of Line2D instances. Note that this function is provided merely for completeness. These lines are re-calculated as the display changes.

New in version 1.1.0.

get_zticks(minor=False)
Return the z ticks as a list of locations See matplotlib.axes.Axes.get_yticks() for more details.

Note: Minor ticks are not supported.

New in version 1.1.0.

grid(b=True, **kwargs)
Set / unset 3D grid.

Note: Currently, this function does not behave the same as matplotlib.axes.Axes.grid(), but it is intended to eventually support that behavior.

Changed in version 1.1.0: This function was changed, but not tested. Please report any bugs.

have_units()
Return True if units are set on the x, y, or z axes

invert_zaxis()
Invert the z-axis.

New in version 1.1.0: This function was added, but not tested. Please report any bugs.
locator_params\( (axis='both', \text{tight}=\text{None}, **\text{kwargs}) \)
Convenience method for controlling tick locators.

See \texttt{matplotlib.axes.Axes.locator_params()} for full documentation Note that this is for Axes3D objects, therefore, setting \texttt{axis} to ‘both’ will result in the parameters being set for all three axes. Also, \texttt{axis} can also take a value of ‘z’ to apply parameters to the z axis.

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

margins\( (*\text{args}, **\text{kw}) \)
Convenience method to set or retrieve autoscaling margins.

\textbf{signatures}:

\begin{verbatim}
    margins()
    returns xmargin, ymargin, zmargin

    margins(margin)
    margins(xmargin, ymargin, zmargin)
    margins(x=xmargin, y=ymargin, z=zmargin)
    margins(..., \text{tight}=\text{False})
\end{verbatim}

All forms above set the xmargin, ymargin and zmargin parameters. All keyword parameters are optional. A single argument specifies xmargin, ymargin and zmargin. The \texttt{tight} parameter is passed to \texttt{autoscale_view()}, which is executed after a margin is changed; the default here is \texttt{True}, on the assumption that when margins are specified, no additional padding to match tick marks is usually desired. Setting \texttt{tight} to \texttt{None} will preserve the previous setting.

Specifying any margin changes only the autoscaling; for example, if \texttt{xmargin} is not \texttt{None}, then \texttt{xmargin} times the X data interval will be added to each end of that interval before it is used in autoscaling.

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

mouse_init\( (rotate\_btn=1, zoom\_btn=3) \)
Initializes mouse button callbacks to enable 3D rotation of the axes. Also optionally sets the mouse buttons for 3D rotation and zooming.

\begin{verbatim}
<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rotate_btn</td>
<td>The integer or list of integers specifying which mouse button or buttons to use for 3D rotation of the axes. Default = 1.</td>
</tr>
<tr>
<td>zoom_btn</td>
<td>The integer or list of integers specifying which mouse button or buttons to use to zoom the 3D axes. Default = 3.</td>
</tr>
</tbody>
</table>
\end{verbatim}

name = ‘3d’

plot\( (xs, ys, *\text{args}, **\text{kwargs}) \)
Plot 2D or 3D data.
<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xs, ys</code></td>
<td>x, y coordinates of vertices</td>
</tr>
<tr>
<td><code>zs</code></td>
<td>z value(s), either one for all points or one for each point.</td>
</tr>
<tr>
<td><code>zdir</code></td>
<td>Which direction to use as z (‘x’, ‘y’ or ‘z’) when plotting a 2D set.</td>
</tr>
</tbody>
</table>

Other arguments are passed on to `plot()`

### `plot3D(xs, ys, *args, **kwargs)`
Plot 2D or 3D data.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xs, ys</code></td>
<td>x, y coordinates of vertices</td>
</tr>
<tr>
<td><code>zs</code></td>
<td>z value(s), either one for all points or one for each point.</td>
</tr>
<tr>
<td><code>zdir</code></td>
<td>Which direction to use as z (‘x’, ‘y’ or ‘z’) when plotting a 2D set.</td>
</tr>
</tbody>
</table>

Other arguments are passed on to `plot()`

### `plot_surface(X, Y, Z, *args, **kwargs)`
Create a surface plot.

By default it will be colored in shades of a solid color, but it also supports color mapping by supplying the `cmap` argument.

The `rstride` and `cstride` kwargs set the stride used to sample the input data to generate the graph. If 1k by 1k arrays are passed in, the default values for the strides will result in a 100x100 grid being plotted. Defaults to 10. Raises a ValueError if both stride and count kwargs (see next section) are provided.

The `rcount` and `ccount` kwargs supersedes `rstride` and `cstride` for default sampling method for surface plotting. These arguments will determine at most how many evenly spaced samples will be taken from the input data to generate the graph. This is the default sampling method unless using the ‘classic’ style. Will raise ValueError if both stride and count are specified. Added in v2.0.0.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>X, Y, Z</code></td>
<td>Data values as 2D arrays</td>
</tr>
<tr>
<td><code>rstride</code></td>
<td>Array row stride (step size)</td>
</tr>
<tr>
<td><code>cstride</code></td>
<td>Array column stride (step size)</td>
</tr>
<tr>
<td><code>rcount</code></td>
<td>Use at most this many rows, defaults to 50</td>
</tr>
<tr>
<td><code>ccount</code></td>
<td>Use at most this many columns, defaults to 50</td>
</tr>
<tr>
<td><code>color</code></td>
<td>Color of the surface patches</td>
</tr>
<tr>
<td><code>cmap</code></td>
<td>A colormap for the surface patches.</td>
</tr>
<tr>
<td><code>facecolors</code></td>
<td>Face colors for the individual patches</td>
</tr>
<tr>
<td><code>norm</code></td>
<td>An instance of Normalize to map values to colors</td>
</tr>
<tr>
<td><code>vmin</code></td>
<td>Minimum value to map</td>
</tr>
<tr>
<td><code>vmax</code></td>
<td>Maximum value to map</td>
</tr>
<tr>
<td><code>shade</code></td>
<td>Whether to shade the facecolors</td>
</tr>
</tbody>
</table>

Other arguments are passed on to `Poly3DCollection`

### `plot_trisurf(*args, **kwargs)`
<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X, Y, Z</td>
<td>Data values as 1D arrays</td>
</tr>
<tr>
<td>color</td>
<td>Color of the surface patches</td>
</tr>
<tr>
<td>cmap</td>
<td>A colormap for the surface patches.</td>
</tr>
<tr>
<td>norm</td>
<td>An instance of Normalize to map values to colors</td>
</tr>
<tr>
<td>vmin</td>
<td>Minimum value to map</td>
</tr>
<tr>
<td>vmax</td>
<td>Maximum value to map</td>
</tr>
<tr>
<td>shade</td>
<td>Whether to shade the facecolors</td>
</tr>
</tbody>
</table>

The (optional) triangulation can be specified in one of two ways; either:

```
plot_trisurf(triangulation, ...)
```

where triangulation is a `Triangulation` object, or:

```
plot_trisurf(X, Y, ...)
plot_trisurf(X, Y, triangles, ...)
plot_trisurf(X, Y, triangles=triangles, ...)
```

in which case a Triangulation object will be created. See `Triangulation` for a explanation of these possibilities.

The remaining arguments are:

```
plot_trisurf(..., Z)
```

where Z is the array of values to contour, one per point in the triangulation.

Other arguments are passed on to `Poly3DCollection`

**Examples:**
New in version 1.2.0: This plotting function was added for the v1.2.0 release.

```python
plot_wireframe(X, Y, Z, *args, **kwargs)
```

Plot a 3D wireframe.

The `rstride` and `cstride` kwargs set the stride used to sample the input data to
generate the graph. If either is 0 the input data in not sampled along this direction producing a 3D line plot rather than a wireframe plot. The stride arguments are only used by default if in the ‘classic’ mode. They are now superseded by rcount and ccount. Will raise ValueError if both stride and count are used.

The rcount and ccount kwargs supersedes rstride and cstride for default sampling method for wireframe plotting. These arguments will determine at most how many evenly spaced samples will be taken from the input data to generate the graph. This is the default sampling method unless using the ‘classic’ style. Will raise ValueError if both stride and count are specified. If either is zero, then the input data is not sampled along this direction, producing a 3D line plot rather than a wireframe plot. Added in v2.0.0.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X, Y, Z</td>
<td>Data values as 2D arrays</td>
</tr>
<tr>
<td>rstride</td>
<td>Array row stride (step size), defaults to 1</td>
</tr>
<tr>
<td>cstride</td>
<td>Array column stride (step size), defaults to 1</td>
</tr>
<tr>
<td>rcount</td>
<td>Use at most this many rows, defaults to 50</td>
</tr>
<tr>
<td>ccount</td>
<td>Use at most this many columns, defaults to 50</td>
</tr>
</tbody>
</table>

Keyword arguments are passed on to LineCollection.

Returns a Line3DCollection

**quiver(**args, **kwargs)**

Plot a 3D field of arrows.

call signatures:

```
quiver(X, Y, Z, U, V, W, **kwargs)
```

Arguments:

- **X, Y, Z**: The x, y and z coordinates of the arrow locations (default is tail of arrow; see pivot kwarg)
- **U, V, W**: The x, y and z components of the arrow vectors

The arguments could be array-like or scalars, so long as they they can be broadcast together. The arguments can also be masked arrays. If an element in any of argument is masked, then that corresponding quiver element will not be plotted.

Keyword arguments:

- **length**: [1.0 | float] The length of each quiver, default to 1.0, the unit is the same with the axes
- **arrow_length_ratio**: [0.3 | float] The ratio of the arrow head with respect to the quiver, default to 0.3
- **pivot**: [‘tail’ | ‘middle’ | ‘tip’] The part of the arrow that is at the grid point; the arrow rotates about this point, hence the name pivot. Default is ‘tail’
normalize: [False | True] When True, all of the arrows will be the same length. This defaults to False, where the arrows will be different lengths depending on the values of u,v,w.

Any additional keyword arguments are delegated to LineCollection

quiver3D(*args, **kwargs)
Plot a 3D field of arrows.

call signatures:

```
quiver(X, Y, Z, U, V, W, **kwargs)
```

Arguments:

- **X, Y, Z**: The x, y and z coordinates of the arrow locations (default is tail of arrow; see **pivot** kwarg)
- **U, V, W**: The x, y and z components of the arrow vectors

The arguments could be array-like or scalars, so long as they they can be broadcast together. The arguments can also be masked arrays. If an element in any of argument is masked, then that corresponding quiver element will not be plotted.

Keyword arguments:

- **length**: [1.0 | float] The length of each quiver, default to 1.0, the unit is the same with the axes
- **arrow_length_ratio**: [0.3 | float] The ratio of the arrow head with respect to the quiver, default to 0.3
- **pivot**: [‘tail’ | ‘middle’ | ‘tip’] The part of the arrow that is at the grid point; the arrow rotates about this point, hence the name **pivot**. Default is ‘tail’
- **normalize**: [False | True] When True, all of the arrows will be the same length. This defaults to False, where the arrows will be different lengths depending on the values of u,v,w.

Any additional keyword arguments are delegated to LineCollection

scatter(xs, ys, zs=0, zdir='z', s=20, c=None, depthshade=True, *args, **kwargs)
Create a scatter plot.
### scatter3D

`scatter3D(xs, ys, zs=0, zdir='z', s=20, c=None, depthshade=True, *args, **kwargs)`

Create a scatter plot.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xs, ys</code></td>
<td>Positions of data points.</td>
</tr>
<tr>
<td><code>zs</code></td>
<td>Either an array of the same length as <code>xs</code> and <code>ys</code> or a single value to place all points in the same plane. Default is 0.</td>
</tr>
<tr>
<td><code>zdir</code></td>
<td>Which direction to use as z ('x', 'y' or 'z') when plotting a 2D set.</td>
</tr>
<tr>
<td><code>s</code></td>
<td>Size in points^2. It is a scalar or an array of the same length as <code>x</code> and <code>y</code>.</td>
</tr>
<tr>
<td><code>c</code></td>
<td>A color. <code>c</code> can be a single color format string, or a sequence of color specifications of length <code>N</code>, or a sequence of <code>N</code> numbers to be mapped to colors using the <code>cmap</code> and <code>norm</code> specified via kwargs (see below). Note that <code>c</code> should not be a single numeric RGB or RGBA sequence because that is indistinguishable from an array of values to be colormapped. <code>c</code> can be a 2-D array in which the rows are RGB or RGBA, however, including the case of a single row to specify the same color for all points.</td>
</tr>
<tr>
<td><code>depthshade</code></td>
<td>Whether or not to shade the scatter markers to give the appearance of depth. Default is <code>True</code>.</td>
</tr>
</tbody>
</table>

Keyword arguments are passed on to `scatter()`. Returns a `Patch3DCollection`.

### set_autoscale_on

`set_autoscale_on(b)`

Set whether autoscaling is applied on plot commands

accepts: `[ True | False ]`
New in version 1.1.0: This function was added, but not tested. Please report any bugs.

```python
set_autoscalez_on(b)
```
Set whether autoscaling for the z-axis is applied on plot commands

accepts: [ True | False ]

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

```python
set_axis_off()
```

```python
set_axis_on()
```

```python
set_axisbelow(b)
```
Set whether the axis ticks and gridlines are above or below most artists

For axes3d objects, this will ignore any settings and just use True

ACCEPTS: [ True | False ]

New in version 1.1.0: This function was added for completeness.

```python
set_frame_on(b)
```
Set whether the 3D axes panels are drawn

ACCEPTS: [ True | False ]

New in version 1.1.0.

```python
set_title(label, fontdict=None, loc='center', **kwargs)
```
Set a title for the axes.

Set one of the three available axes titles. The available titles are positioned above the axes in the center, flush with the left edge, and flush with the right edge.

**Parameters**

`label` : str
   Text to use for the title

`fontdict` : dict
   A dictionary controlling the appearance of the title text, the default `fontdict` is:

   ```
   {'fontsize': rcParams['axes.titlesize'],
    'fontweight': rcParams['axes.titleweight'],
    'verticalalignment': 'baseline',
    'horizontalalignment': loc}
   ```

`loc` : {‘center’, ‘left’, ‘right’}, str, optional
   Which title to set, defaults to ‘center’

**Returns**

`text` : `Text`
   The matplotlib text instance representing the title
**Other Parameters** `kwargs` : text properties

Other keyword arguments are text properties, see `Text` for a list of valid text properties.

```python
set_top_view()
```

```python
set_xlim(left=None, right=None, emit=True, auto=False, **kw)
```

Set 3D x limits.

See `matplotlib.axes.Axes.set_xlim()` for full documentation.

```python
set_xlim3d(left=None, right=None, emit=True, auto=False, **kw)
```

Set 3D x limits.

See `matplotlib.axes.Axes.set_xlim()` for full documentation.

```python
set_xscale(value, **kwargs)
```

Set the x-axis scale

Set the scaling of the x-axis: 'linear' | 'log' | 'logit' | 'symlog'

**ACCEPTS**: ['linear' | 'log' | 'logit' | 'symlog']

**Different kwargs are accepted, depending on the scale**: 'linear'

'log'

- `basex/basey`: The base of the logarithm
- `nonposx/nonposy`: ['mask' | 'clip'] non-positive values in x or y can be masked as invalid, or clipped to a very small positive number
- `subsx/subsy`: Where to place the subticks between each major tick. Should be a sequence of integers. For example, in a log10 scale: [2, 3, 4, 5, 6, 7, 8, 9]

  will place 8 logarithmically spaced minor ticks between each major tick.

'logit'

- `nonpos`: ['mask' | 'clip'] values beyond ]0, 1[ can be masked as invalid, or clipped to a number very close to 0 or 1

'symlog'

- `basex/basey`: The base of the logarithm
- `linthreshx/linthreshy`: The range (-x, x) within which the plot is linear (to avoid having the plot go to infinity around zero).
- `subsx/subsy`: Where to place the subticks between each major tick. Should be a sequence of integers. For example, in a log10 scale: [2, 3, 4, 5, 6, 7, 8, 9]

  will place 8 logarithmically spaced minor ticks between each major tick.
**linscalex/linscaley:** This allows the linear range \((-\text{linthresh} \text{ to } \text{linthresh})\) to be stretched relative to the logarithmic range. Its value is the number of decades to use for each half of the linear range. For example, when \(\text{linscale} == 1.0\) (the default), the space used for the positive and negative halves of the linear range will be equal to one decade in the logarithmic range.

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

```python
set_ylim(bottom=None, top=None, emit=True, auto=False, **kw)
```

Set 3D y limits.

See `matplotlib.axes.Axes.set_ylim()` for full documentation.

```python
set_ylim3d(bottom=None, top=None, emit=True, auto=False, **kw)
```

Set 3D y limits.

See `matplotlib.axes.Axes.set_ylim()` for full documentation.

```python
set_yscale(value, **kwargs)
```

Set the y-axis scale

Set the scaling of the y-axis: ‘linear’ | ‘log’ | ‘logit’ | ‘symlog’

ACCEPTS: [‘linear’ | ‘log’ | ‘logit’ | ‘symlog’]

**Different kwargs are accepted, depending on the scale: ‘linear’**

‘log’

```python
basex/basey: The base of the logarithm
```

**nonposx/nonposy:** [‘mask’ | ‘clip’] non-positive values in \(x\) or \(y\) can be masked as invalid, or clipped to a very small positive number

```python
subsx/subsy: Where to place the subticks between each major tick. Should be a sequence of integers. For example, in a log10 scale: \([2, 3, 4, 5, 6, 7, 8, 9]\)
```

will place 8 logarithmically spaced minor ticks between each major tick.

‘logit’

```python
nonpos: [‘mask’ | ‘clip’] values beyond \([0, 1]\) can be masked as invalid, or clipped to a number very close to 0 or 1
```

‘symlog’

```python
basex/basey: The base of the logarithm
```

**linthreshx/linthreshy:** The range \((-x, x)\) within which the plot is linear (to avoid having the plot go to infinity around zero).

```python
subsx/subsy: Where to place the subticks between each major tick. Should be a sequence of integers. For example, in a log10 scale: \([2, 3, 4, 5, 6, 7, 8, 9]\)
```

will place 8 logarithmically spaced minor ticks between each major tick.
**linscalex/linscaley**: This allows the linear range (-linthresh to linthresh) to be stretched relative to the logarithmic range. Its value is the number of decades to use for each half of the linear range. For example, when linscale == 1.0 (the default), the space used for the positive and negative halves of the linear range will be equal to one decade in the logarithmic range.

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

```python
set_zbound(lower=None, upper=None)
```
Set the lower and upper numerical bounds of the z-axis. This method will honor axes inversion regardless of parameter order. It will not change the _autoscaleZon attribute.

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

```python
set_zlabel(zlabel, fontdict=None, labelpad=None, **kwargs)
```
Set zlabel. See doc for `set_ylabel()` for description.

```python
set_zlim(bottom=None, top=None, emit=True, auto=False, **kw)
```
Set 3D z limits.

See `matplotlib.axes.Axes.set_ylim()` for full documentation

```python
set_zlim3d(bottom=None, top=None, emit=True, auto=False, **kw)
```
Set 3D z limits.

See `matplotlib.axes.Axes.set_ylim()` for full documentation

```python
set_zmargin(m)
```
Set padding of Z data limits prior to autoscaling.

\[ m \times \text{data interval} \] will be added to each end of that interval before it is used in autoscaling.

accepts: float in range 0 to 1

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

```python
set_zscale(value, **kwargs)
```
Set the scaling of the z-axis: ‘linear’ | ‘log’ | ‘logit’ | ‘symlog’

ACCEPTS: [‘linear’ | ‘log’ | ‘logit’ | ‘symlog’]

**Different kwargs are accepted, depending on the scale: ‘linear’**

`‘log’`

`baseX/baseY`: The base of the logarithm

`nonposX/nonposY`: [‘mask’ | ‘clip’] non-positive values in x or y can be masked as invalid, or clipped to a very small positive number

`subX/subY`: Where to place the subticks between each major tick. Should be a sequence of integers. For example, in a log10 scale: [2, 3, 4, 5, 6, 7, 8, 9]

will place 8 logarithmically spaced minor ticks between each major tick.

`‘logit’`
nonpos: ['mask' | 'clip'] values beyond ]0, 1[ can be masked as invalid, or clipped to a number very close to 0 or 1

'symlog'

basex/basey: The base of the logarithm

linthreshx/linthreshy: The range (-x, x) within which the plot is linear (to avoid having the plot go to infinity around zero).

subsx/subsy: Where to place the subticks between each major tick. Should be a sequence of integers. For example, in a log10 scale: [2, 3, 4, 5, 6, 7, 8, 9]

will place 8 logarithmically spaced minor ticks between each major tick.

linscalex/linscaley: This allows the linear range (-linthresh to linthresh) to be stretched relative to the logarithmic range. Its value is the number of decades to use for each half of the linear range. For example, when linscale == 1.0 (the default), the space used for the positive and negative halves of the linear range will be equal to one decade in the logarithmic range.

Note: Currently, Axes3D objects only supports linear scales. Other scales may or may not work, and support for these is improving with each release.

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

set_zticklabels(*args, **kwargs)
Set z-axis tick labels. See matplotlib.axes.Axes.set_yticklabels() for more details.

Note: Minor ticks are not supported by Axes3D objects.

New in version 1.1.0.

set_zticks(*args, **kwargs)
Set z-axis tick locations. See matplotlib.axes.Axes.set_yticks() for more details.

Note: Minor ticks are not supported.

New in version 1.1.0.

text(x, y, z, s, zdir=None, **kwargs)
Add text to the plot. kwvars will be passed on to Axes.text, except for the zdir keyword, which sets the direction to be used as the z direction.

text2D(x, y, s, fontdict=None, withdash=False, **kwargs)
Add text to the axes.

Add text in string s to axis at location x, y, data coordinates.

Parameters x, y : scalars
data coordinates

s : string
text

fontdict : dictionary, optional, default: None
A dictionary to override the default text properties. If fontdict is None, the
defaults are determined by your rc parameters.

withdash : boolean, optional, default: False
Creates a TextWithDash instance instead of a Text instance.

Other Parameters:

kwarg : Text properties.
Other miscellaneous text parameters.

Examples

Individual keyword arguments can be used to override any given parameter:

```python
>>> text(x, y, s, fontsize=12)
```

The default transform specifies that text is in data coords, alternatively, you can specify text in
axis coords (0,0 is lower-left and 1,1 is upper-right). The example below places text in the center
of the axes:

```python
>>> text(0.5, 0.5, 'matplotlib', horizontalalignment='center',
...       verticalalignment='center',
...       transform=ax.transAxes)
```

You can put a rectangular box around the text instance (e.g., to set a background color) by using
the keyword bbox. bbox is a dictionary of Rectangle properties. For example:

```python
>>> text(x, y, s, bbox=dict(facecolor='red', alpha=0.5))
```

text3D(x, y, z, s, zdir=None, **kwargs)
Add text to the plot. kwargs will be passed on to Axes.text, except for the zdir keyword, which
sets the direction to be used as the z direction.

tick_params(axis='both', **kwargs)
Convenience method for changing the appearance of ticks and tick labels.

See matplotlib.axes.Axes.tick_params() for more complete documentation.

The only difference is that setting axis to ‘both’ will mean that the settings are applied to all
three axes. Also, the axis parameter also accepts a value of ‘z’, which would mean to apply to
only the z-axis.

Also, because of how Axes3D objects are drawn very differently from regular 2D axes, some of
these settings may have ambiguous meaning. For simplicity, the ‘z’ axis will accept settings as
if it was like the ‘y’ axis.
Note: While this function is currently implemented, the core part of the Axes3D object may ignore some of these settings. Future releases will fix this. Priority will be given to those who file bugs.

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

**ticklabel_format(**kwargs)**

Convenience method for manipulating the ScalarFormatter used by default for linear axes in Axes3D objects.

See `matplotlib.axes.Axes.ticklabel_format()` for full documentation. Note that this version applies to all three axes of the Axes3D object. Therefore, the `axis` argument will also accept a value of ‘z’ and the value of ‘both’ will apply to all three axes.

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

**tricontour(**args, **kwargs)**

Create a 3D contour plot.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X, Y, Z</td>
<td>Data values as numpy.arrays</td>
</tr>
<tr>
<td>extend3d</td>
<td>Whether to extend contour in 3D (default: False)</td>
</tr>
<tr>
<td>stride</td>
<td>Stride (step size) for extending contour</td>
</tr>
<tr>
<td>zdir</td>
<td>The direction to use: x, y or z (default)</td>
</tr>
<tr>
<td>offset</td>
<td>If specified plot a projection of the contour lines on this position in plane normal to zdir</td>
</tr>
</tbody>
</table>

Other keyword arguments are passed on to `tricontour()`

Returns a `contour`

Changed in version 1.3.0: Added support for custom triangulations

EXPERIMENTAL: This method currently produces incorrect output due to a longstanding bug in 3D PolyCollection rendering.

**tricontourf(**args, **kwargs)**

Create a 3D contourf plot.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X, Y, Z</td>
<td>Data values as numpy.arrays</td>
</tr>
<tr>
<td>zdir</td>
<td>The direction to use: x, y or z (default)</td>
</tr>
<tr>
<td>offset</td>
<td>If specified plot a projection of the contour lines on this position in plane normal to zdir</td>
</tr>
</tbody>
</table>

Other keyword arguments are passed on to `tricontour()`

Returns a `contour`
Changed in version 1.3.0: Added support for custom triangulations

EXPERIMENTAL: This method currently produces incorrect output due to a longstanding bug in 3D PolyCollection rendering.

tunit_cube(vals=None, M=None)

tunit_edges(vals=None, M=None)

unit_cube(vals=None)

update_datalim(xys, **kwargs)

view_init(elev=None, azim=None)
Set the elevation and azimuth of the axes.
This can be used to rotate the axes programatically.
‘elev’ stores the elevation angle in the z plane. ‘azim’ stores the azimuth angle in the x,y plane.
if elev or azim are None (default), then the initial value is used which was specified in the Axes3D constructor.

zaxis_date(tz=None)
Sets up z-axis ticks and labels that treat the z data as dates.
tz is a timezone string or tzinfo instance. Defaults to rc value.

Note: This function is merely provided for completeness. Axes3D objects do not officially support dates for ticks, and so this may or may not work as expected.

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

zaxis_inverted()
Returns True if the z-axis is inverted.
New in version 1.1.0: This function was added, but not tested. Please report any bugs.

mpl_toolkits.mplot3d.axes3d.get_test_data(delta=0.05)
Return a tuple X, Y, Z with a test data set.

mpl_toolkits.mplot3d.axes3d.unit_bbox()

69.2.2 axis3d

Note: Historically, axis3d has suffered from having hard-coded constants controlling the look and feel of the 3D plot. This precluded user level adjustments such as label spacing, font colors and panel colors.
For version 1.1.0, these constants have been consolidated into a single private member dictionary, `self._axinfo`, for the axis object. This is intended only as a stop-gap measure to allow user-level customization, but it is not intended to be permanent.

```python
class mpl_toolkits.mplot3d.axis3d.Axis(adir, v_intervalx, d_intervalx, axes, *args, **kwargs)
    Bases: matplotlib.axis.XAxis
draw(renderer)
draw_pane(renderer)
get_major_ticks(numticks=None)
get_rotate_label(text)
get_tick_positions()
get_tightbbox(renderer)
get_view_interval()
    return the Interval instance for this 3d axis view limits
init3d()
set_pane_color(color)
    Set pane color to a RGBA tuple
set_pane_pos(xys)
set_rotate_label(val)
    Whether to rotate the axis label: True, False or None. If set to None the label will be rotated if longer than 4 chars.
set_view_interval(vmin, vmax, ignore=False)
```

```python
class mpl_toolkits.mplot3d.axis3d.XAxis(adir, v_intervalx, d_intervalx, axes, *args, **kwargs)
    Bases: mpl_toolkits.mplot3d.axis3d.Axis
get_data_interval()
    return the Interval instance for this axis data limits
class mpl_toolkits.mplot3d.axis3d.YAxis(adir, v_intervalx, d_intervalx, axes, *args, **kwargs)
    Bases: mpl_toolkits.mplot3d.axis3d.Axis
```
get_data_interval()
return the Interval instance for this axis data limits

class mpl_toolkits.mplot3d.axis3d.ZAxis(adir, v_intervalx, d_intervalx, axes, *args, **kwargs)
Bases: mpl_toolkits.mplot3d.axis3d.Axis

get_data_interval()
return the Interval instance for this axis data limits

mpl_toolkits.mplot3d.axis3d.get_flip_min_max(coord, index, mins, maxs)

mpl_toolkits.mplot3d.axis3d.move_from_center(coord, centers, deltas, axmask=(True, True, True))

Return a coordinate that is moved by “deltas” away from the center.

mpl_toolkits.mplot3d.axis3d.tick_update_position(tick, tickxs, tickys, labelpos)

Update tick line and label position and style.

### 69.2.3 art3d

Module containing 3D artist code and functions to convert 2D artists into 3D versions which can be added to an Axes3D.

class mpl_toolkits.mplot3d.art3d.Line3D(xs, ys, zs, *args, **kwargs)
Bases: matplotlib.lines.Line2D

3D line object.

Keyword arguments are passed onto Line2D().

draw(renderer)

set_3d_properties(zs=0, zdir='z')

class mpl_toolkits.mplot3d.art3d.Line3DCollection(segments, *args, **kwargs)
Bases: matplotlib.collections.LineCollection

A collection of 3D lines.

Keyword arguments are passed onto LineCollection().

do_3d_projection(renderer)

Project the points according to renderer matrix.

draw(renderer, project=False)

set_segments(segments)
Set 3D segments

set_sort_zpos(val)
Set the position to use for z-sorting.
class mpl_toolkits.mplot3d.art3d.Patch3D(*args, **kwargs)
    Bases: matplotlib.patches.Patch
    3D patch object.
    
    do_3d_projection(renderer)

    draw(renderer)

    get_facecolor()

    get_path()

    set_3d_properties(verts, zs=0, zdir='z')

class mpl_toolkits.mplot3d.art3d.Patch3DCollection(*args, **kwargs)
    Bases: matplotlib.collections.PatchCollection
    A collection of 3D patches.
    Create a collection of flat 3D patches with its normal vector pointed in zdir direction, and located at zs on the zdir axis. ‘zs’ can be a scalar or an array-like of the same length as the number of patches in the collection.
    Constructor arguments are the same as for PatchCollection. In addition, keywords zs=0 and zdir='z' are available.
    Also, the keyword argument “depthshade” is available to indicate whether or not to shade the patches in order to give the appearance of depth (default is True). This is typically desired in scatter plots.
    do_3d_projection(renderer)

    set_3d_properties(zs, zdir)

    set_sort_zpos(val)
        Set the position to use for z-sorting.

class mpl_toolkits.mplot3d.art3d.Path3DCollection(*args, **kwargs)
    Bases: matplotlib.collections.PathCollection
    A collection of 3D paths.
    Create a collection of flat 3D paths with its normal vector pointed in zdir direction, and located at zs on the zdir axis. ‘zs’ can be a scalar or an array-like of the same length as the number of paths in the collection.
    Constructor arguments are the same as for PathCollection. In addition, keywords zs=0 and zdir='z' are available.
Also, the keyword argument “depthshade” is available to indicate whether or not to shade the patches in order to give the appearance of depth (default is True). This is typically desired in scatter plots.

```python
do_3d_projection(renderer)
```

```python
set_3d_properties(zs, zdir)
```

```python
set_sort_zpos(val)
```

Set the position to use for z-sorting.

```python
class mpl_toolkits.mplot3d.art3d.PathPatch3D(path, **kwargs)
```

Bases: `mpl_toolkits.mplot3d.art3d.Patch3D`

3D PathPatch object.

```python
do_3d_projection(renderer)
```

```python
set_3d_properties(path, zs=0, zdir='z')
```

```python
class mpl_toolkits.mplot3d.art3d.Poly3DCollection(verts, *args, **kwargs)
```

Bases: `matplotlib.collections.PolyCollection`

A collection of 3D polygons.

Create a Poly3DCollection.

`verts` should contain 3D coordinates.

Keyword arguments: zsort, see set_zsort for options.

Note that this class does a bit of magic with the _facecolors and _edgecolors properties.

```python
do_3d_projection(renderer)
```

Perform the 3D projection for this object.

```python
draw(renderer)
```

```python
get_edgecolor()
```

```python
get_edgecolors()
```

```python
get_facecolor()
```

```python
get_facecolors()
```

```python
get_vector(segments3d)
```

Optimize points for projection.
set_3d_properties()

set_alpha(alpha)
    Set the alpha transparencies of the collection. alpha must be a float or None.
    ACCEPTS: float or None

set_edgecolor(colors)

set_edgecolors(colors)

set_facecolor(colors)

set_facecolors(colors)

set_sort_zpos(val)
    Set the position to use for z-sorting.

set_verts(verts, closed=True)
    Set 3D vertices.

set_verts_and_codes(verts, codes)
    Sets 3D vertices with path codes

set_zsort(zsort)

    Set z-sorting behaviour: boolean: if True use default ‘average’ string: ‘average’, ‘min’ or ‘max’

class mpl_toolkits.mplot3d.art3d.Text3D(x=0, y=0, z=0, text='', zdir='z', **kwargs)
    Bases: matplotlib.text.Text
    Text object with 3D position and (in the future) direction.
    x, y, z Position of text text Text string to display zdir Direction of text
    Keyword arguments are passed onto Text().

draw(renderer)

    set_3d_properties(z=0, zdir='z')

mpl_toolkits.mplot3d.art3d.get_colors(c, num)
    Stretch the color argument to provide the required number num

mpl_toolkits.mplot3d.art3d.get_dir_vector(zdir)

mpl_toolkits.mplot3d.art3d.get_patch_verts(patch)
    Return a list of vertices for the path of a patch.
mpl_toolkits.mplot3d.art3d.iscolor(c)

mpl_toolkits.mplot3d.art3d.juggle_axes(xs, ys, zs, zdir)
Reorder coordinates so that 2D xs, ys can be plotted in the plane orthogonal to zdir. zdir is normally x, y or z. However, if zdir starts with a ‘-’ it is interpreted as a compensation for rotate_axes.

mpl_toolkits.mplot3d.art3d.line_2d_to_3d(line, zs=0, zdir='z')
Convert a 2D line to 3D.

mpl_toolkits.mplot3d.art3d.line_collection_2d_to_3d(col, zs=0, zdir='z')
Convert a LineCollection to a Line3DCollection object.

mpl_toolkits.mplot3d.art3d.norm_angle(a)
Return angle between -180 and +180

mpl_toolkits.mplot3d.art3d.norm_text_angle(a)
Return angle between -90 and +90

mpl_toolkits.mplot3d.art3d.patch_2d_to_3d(patch, z=0, zdir='z')
Convert a Patch to a Patch3D object.

mpl_toolkits.mplot3d.art3d.patch_collection_2d_to_3d(col, zs=0, zdir='z')
Convert a PathCollection into a Patch3DCollection object (or a PathCollection into a Path3DCollection object).

Keywords:

za The location or locations to place the patches in the collection along the zdir axis. Defaults to 0.

zdir The axis in which to place the patches. Default is “z”.

depthshade Whether to shade the patches to give a sense of depth. Defaults to True.

mpl_toolkits.mplot3d.art3d.path_to_3d_segment(path, zs=0, zdir='z')
Convert a path to a 3D segment.

mpl_toolkits.mplot3d.art3d.path_to_3d_segment_with_codes(path, zs=0, zdir='z')
Convert a path to a 3D segment with path codes.

mpl_toolkits.mplot3d.art3d.pathpatch_2d_to_3d(pathpatch, z=0, zdir='z')
Convert a PathPatch to a PathPatch3D object.

mpl_toolkits.mplot3d.art3d.paths_to_3d_segments(paths, zs=0, zdir='z')
Convert paths from a collection object to 3D segments.

mpl_toolkits.mplot3d.art3d.paths_to_3d_segments_with_codes(paths, zs=0, zdir='z')
Convert paths from a collection object to 3D segments with path codes.

mpl_toolkits.mplot3d.art3d.poly_collection_2d_to_3d(col, zs=0, zdir='z')
Convert a PolyCollection to a Poly3DCollection object.

mpl_toolkits.mplot3d.art3d.rotate_axes(xs, ys, zs, zdir)
Reorder coordinates so that the axes are rotated with zdir along the original z axis. Prepending the axis with a ‘-’ does the inverse transform, so zdir can be x, -x, y, -y, z or -z
mpl_toolkits.mplot3d.art3d.text_2d_to_3d(obj, z=0, zdir='z')
    Convert a Text to a Text3D object.

mpl_toolkits.mplot3d.art3d.zalpha(colors, zs)
    Modify the alphas of the color list according to depth

69.2.4 proj3d

Various transforms used for by the 3D code

mpl_toolkits.mplot3d.proj3d.inv_transform(xs, ys, zs, M)

mpl_toolkits.mplot3d.proj3d.line2d(p0, p1)
    Return 2D equation of line in the form ax+by+c = 0

mpl_toolkits.mplot3d.proj3d.line2d_dist(l, p)
    Distance from line to point line is a tuple of coefficients a,b,c

mpl_toolkits.mplot3d.proj3d.line2d_seg_dist(p1, p2, p0)
    distance(s) from line defined by p1 - p2 to point(s) p0
    p0[0] = x(s) p0[1] = y(s)
    intersection point p = p1 + u*(p2-p1) and intersection point lies within segment if u is between 0 and 1

mpl_toolkits.mplot3d.proj3d.mod(v)
    3d vector length

mpl_toolkits.mplot3d.proj3d.persp_transformation(zfront, zback)

mpl_toolkits.mplot3d.proj3d.proj_points(points, M)

mpl_toolkits.mplot3d.proj3d.proj_trans_clip_points(points, M)

mpl_toolkits.mplot3d.proj3d.proj_trans_points(points, M)

mpl_toolkits.mplot3d.proj3d.proj_transform(xs, ys, zs, M)
    Transform the points by the projection matrix

mpl_toolkits.mplot3d.proj3d.proj_transform_clip(xs, ys, zs, M)
    Transform the points by the projection matrix and return the clipping result returns txs,tsytsz,tis

mpl_toolkits.mplot3d.proj3d.proj_transform_vec(vec, M)

mpl_toolkits.mplot3d.proj3d.proj_transform_vec_clip(vec, M)
mpl_toolkits.mplot3d.proj3d.rot_x(V, alpha)

mpl_toolkits.mplot3d.proj3d.test_lines_dists()

mpl_toolkits.mplot3d.proj3d.test_proj()

mpl_toolkits.mplot3d.proj3d.test_proj_draw_axes(M, s=1)

mpl_toolkits.mplot3d.proj3d.test_proj_make_M(E=None)

mpl_toolkits.mplot3d.proj3d.test_rot()

mpl_toolkits.mplot3d.proj3d.test_world()

mpl_toolkits.mplot3d.proj3d.transform(xs, ys, zs, M)
    Transform the points by the projection matrix

mpl_toolkits.mplot3d.proj3d.vec_pad_ones(xs, ys, zs)

mpl_toolkits.mplot3d.proj3d.view_transformation(E, R, V)

mpl_toolkits.mplot3d.proj3d.world_transformation(xmin, xmax, ymin, ymax, zmin, zmax)

### 69.3 mplot3d FAQ

#### 69.3.1 How is mplot3d different from MayaVi?

MayaVi2 is a very powerful and featureful 3D graphing library. For advanced 3D scenes and excellent rendering capabilities, it is highly recommended to use MayaVi2.

mplot3d was intended to allow users to create simple 3D graphs with the same “look-and-feel” as matplotlib’s 2D plots. Furthermore, users can use the same toolkit that they are already familiar with to generate both their 2D and 3D plots.

#### 69.3.2 My 3D plot doesn’t look right at certain viewing angles

This is probably the most commonly reported issue with mplot3d. The problem is that – from some viewing angles – a 3D object would appear in front of another object, even though it is physically behind it. This can result in plots that do not look “physically correct.”
Unfortunately, while some work is being done to reduce the occurrence of this artifact, it is currently an intractable problem, and can not be fully solved until matplotlib supports 3D graphics rendering at its core.

The problem occurs due to the reduction of 3D data down to 2D + z-order scalar. A single value represents the 3rd dimension for all parts of 3D objects in a collection. Therefore, when the bounding boxes of two collections intersect, it becomes possible for this artifact to occur. Furthermore, the intersection of two 3D objects (such as polygons or patches) can not be rendered properly in matplotlib’s 2D rendering engine.

This problem will likely not be solved until OpenGL support is added to all of the backends (patches are greatly welcomed). Until then, if you need complex 3D scenes, we recommend using MayaVi.

69.3.3 I don’t like how the 3D plot is laid out, how do I change that?

Historically, mplot3d has suffered from a hard-coding of parameters used to control visuals such as label spacing, tick length, and grid line width. Work is being done to eliminate this issue. For matplotlib v1.1.0, there is a semi-official manner to modify these parameters. See the note in the axis3d section of the mplot3d API documentation for more information.
Part VI

Toolkits
Toolkits are collections of application-specific functions that extend matplotlib.
70.1 Basemap

(Not distributed with matplotlib)

Plots data on map projections, with continental and political boundaries, see basemap docs.

70.2 Cartopy

(Not distributed with matplotlib)

An alternative mapping library written for matplotlib v1.2 and beyond. Cartopy builds on top of matplotlib to provide object oriented map projection definitions and close integration with Shapely for powerful yet
easy-to-use vector data processing tools. An example plot from the Cartopy gallery:

**US States which intersect the track of Hurricane Katrina (2005)**

- **State directly intersects with track**
- **State is within 2 degrees of track**
71.1 mplot3d

`mpl_toolkits.mplot3d` provides some basic 3D plotting (scatter, surf, line, mesh) tools. Not the fastest or feature complete 3D library out there, but ships with matplotlib and thus may be a lighter weight solution for some use cases.
71.2 AxesGrid

The matplotlib AxesGrid toolkit is a collection of helper classes to ease displaying multiple images in matplotlib. The AxesGrid toolkit is distributed with matplotlib source.

![AxesGrid Example](image)

## 71.3 mplcursors

mplcursors provides interactive data cursors for matplotlib.

## 71.4 MplDataCursor

*(Not distributed with matplotlib)*

MplDataCursor is a toolkit written by Joe Kington to provide interactive “data cursors” (clickable annotation boxes) for matplotlib.

## 71.5 GTK Tools

mpl_toolkits.gtktools provides some utilities for working with GTK. This toolkit ships with matplotlib, but requires pygtk.

## 71.6 Excel Tools

mpl_toolkits.exceltools provides some utilities for working with Excel. This toolkit ships with matplotlib, but requires xlwt
71.7 Natgrid

(Not distributed with matplotlib)

mpl_toolkits.natgrid is an interface to natgrid C library for gridding irregularly spaced data. This requires a separate installation of the natgrid toolkit.

71.8 Matplotlib-Venn

(Not distributed with matplotlib)

Matplotlib-Venn provides a set of functions for plotting 2- and 3-set area-weighted (or unweighted) Venn diagrams.

71.9 mplstereonet

(Not distributed with matplotlib)

mplstereonet provides stereonets for plotting and analyzing orientation data in Matplotlib.
Several projects have started to provide a higher-level interface to matplotlib. These are independent projects.

72.1 seaborn

*(Not distributed with matplotlib)*

seaborn is a high level interface for drawing statistical graphics with matplotlib. It aims to make visualization a central part of exploring and understanding complex datasets.

72.2 holoviews

*(Not distributed with matplotlib)*

holoviews makes it easier to visualize data interactively, especially in a Jupyter notebook, by providing a set of declarative plotting objects that store your data and associated metadata. Your data is then immediately visualizable alongside or overlaid with other data, either statically or with automatically provided widgets for parameter exploration.
import numpy as np
import holoviews as hv
hv.notebook_extension('matplotlib')
fractal = hv.Image(np.load('mandelbrot.npy'))
((fractal * hv.HLine(y=0)).hist() + fractal.sample(y=0))

72.3 ggplot

(Not distributed with matplotlib)

ggplot is a port of the R ggplot2 to python based on matplotlib.

72.4 prettyplotlib

(Not distributed with matplotlib)

prettyplotlib is an extension to matplotlib which changes many of the defaults to make plots some consider more attractive.
72.5 iTerm2 terminal backend

(Not distributed with matplotlib)

`matplotlib.iterm2` is an external matplotlib backend uses iTerm2 nightly build inline image display feature.

The Matplotlib Developers’ Guide
This project is a community effort, and everyone is welcome to contribute.
The project is hosted on https://github.com/matplotlib/matplotlib

## 76.1 Submitting a bug report

If you find a bug in the code or documentation, do not hesitate to submit a ticket to the Bug Tracker. You are also welcome to post feature requests or pull requests.

## 76.2 Retrieving and installing the latest version of the code

When working on the Matplotlib source, setting up a virtual environment or a conda environment is recommended.

**Warning:** If you already have a version of Matplotlib installed, use an virtual environment or uninstall using the same method you used to install it. Installing multiple versions of Matplotlib via different methods into the same environment may not always work as expected.

We use Git for version control and GitHub for hosting our main repository.

You can check out the latest sources with the command (see *Set up your fork* for more details):

```bash
git clone git@github.com:matplotlib/matplotlib.git
```

and navigate to the matplotlib directory.

To make sure the tests run locally you must build against the correct version of freetype. To configure the build system to fetch and build it either export the env MPLLOCALFREETYPE as:

```bash
export MPLLOCALFREETYPE=1
```

or copy setup.cfg.template to setup.cfg and edit it to contain
To install Matplotlib (and compile the c-extensions) run the following command from the top-level directory:

```
pip install -v -e ./
```

This installs Matplotlib in ‘editable/develop mode’, i.e., builds everything and places the correct link entries in the install directory so that python will be able to import Matplotlib from the source directory. Thus, any changes to the *.py files will be reflected the next time you import the library. If you change the c-extension source (which might happen if you change branches) you will need to run:

```
python setup.py build
```

or re-run `pip install -v -e ./`.

Alternatively, if you do

```
pip install -v ./
```

all of the files will be copied to the installation directory however, you will have to rerun this command every time the source is changed. Additionally you will need to copy `setup.cfg.template` to `setup.cfg` and edit it to contain:

```
[test]
local_freetype = True
tests = True
```

In either case you can then run the tests to check your work environment is set up properly:

```
python tests.py
```

---

**Note:** Additional dependencies for testing: nose (version 1.0 or later), mock (if python < 3.3), Ghostscript, Inkscape

---

### 76.3 Contributing code

#### 76.3.1 How to contribute

The preferred way to contribute to Matplotlib is to fork the main repository on GitHub, then submit a “pull request” (PR):

1. Create an account on GitHub if you do not already have one.
2. Fork the project repository: click on the ‘Fork’ button near the top of the page. This creates a copy of the code under your account on the GitHub server.

3. Clone this copy to your local disk:

```bash
$ git clone git@github.com:YourLogin/matplotlib.git
```

4. Create a branch to hold your changes:

```bash
$ git checkout -b my-feature origin/master
```

and start making changes. Never work in the master branch!

5. Work on this copy, on your computer, using Git to do the version control. When you’re done editing e.g., `lib/matplotlib/collections.py`, do:

```bash
$ git add lib/matplotlib/collections.py
$ git commit
```

to record your changes in Git, then push them to GitHub with:

```bash
$ git push -u origin my-feature
```

Finally, go to the web page of your fork of the Matplotlib repo, and click ‘Pull request’ to send your changes to the maintainers for review. You may want to consider sending an email to the mailing list for more visibility.

**See also:**

### 76.3.2 Contributing pull requests

It is recommended to check that your contribution complies with the following rules before submitting a pull request:

- If your pull request addresses an issue, please use the title to describe the issue and mention the issue number in the pull request description to ensure a link is created to the original issue.
- All public methods should have informative docstrings with sample usage when appropriate. Use the numpy docstring standard
- Formatting should follow PEP8 recommendation. You should consider installing/enabling automatic PEP8 checking in your editor. Part of the test suite is checking PEP8 compliance, things go smoother if the code is mostly PEP8 compliant to begin with.
- Each high-level plotting function should have a simple example in the *Example* section of the docstring. This should be as simple as possible to demonstrate the method. More complex examples should go in the *examples* tree.
• Changes (both new features and bugfixes) should be tested. See *Developer’s tips for testing* for more details.

• Import the following modules using the standard scipy conventions:

```python
import numpy as np
import numpy.ma as ma
import matplotlib as mpl
import matplotlib.pyplot as plt
import matplotlib.cbook as cbook
import matplotlib.patches as mpatches
```

• If your change is a major new feature, add an entry to the What's new section by adding a new file in `doc/users/whats_new` (see `doc/users/whats_new/README` for more information).

• If you change the API in a backward-incompatible way, please document it in `doc/api/api_changes`, by adding a new file describing your changes (see `doc/api/api_changes/README` for more information).

• See below for additional points about *Keyword argument processing*, if code in your pull request does that.

In addition, you can check for common programming errors with the following tools:

• Code with a good unittest coverage (at least 70%, better 100%), check with:

```bash
pip install coverage
python tests.py --with-coverage
```

• No pyflakes warnings, check with:

```bash
pip install pyflakes
pyflakes path/to/module.py
```

**Note:** The current state of the Matplotlib code base is not compliant with all of those guidelines, but we expect that enforcing those constraints on all new contributions will move the overall code base quality in the right direction.

**See also:**

• *Coding guidelines*

• *Developer’s tips for testing*

• *Developer’s tips for documenting matplotlib*

### 76.3.3 Issues for New Contributors

New contributors should look for the following tags when looking for issues. We strongly recommend that new contributors tackle *new-contributor-friendly* issues (easy, well documented issues, that do not require
an understanding of the different submodules of Matplotlib) and Easy-fix issues. This helps the contributor become familiar with the contribution workflow, and for the core devs to become acquainted with the contributor; besides which, we frequently underestimate how easy an issue is to solve!

### 76.4 Other ways to contribute

Code is not the only way to contribute to Matplotlib. For instance, documentation is also a very important part of the project and often doesn’t get as much attention as it deserves. If you find a typo in the documentation, or have made improvements, do not hesitate to send an email to the mailing list or submit a GitHub pull request. Full documentation can be found under the doc/ directory.

It also helps us if you spread the word: reference the project from your blog and articles or link to it from your website!

### 76.5 Coding guidelines

#### 76.5.1 New modules and files: installation

- If you have added new files or directories, or reorganized existing ones, make sure the new files are included in the match patterns in MANIFEST.in, and/or in package_data in setup.py.

#### 76.5.2 C/C++ extensions

- Extensions may be written in C or C++.
- Code style should conform to PEP7 (understanding that PEP7 doesn’t address C++, but most of its admonitions still apply).
- Python/C interface code should be kept separate from the core C/C++ code. The interface code should be named F00_wrap.cpp or F00_wrapper.cpp.
- Header file documentation (aka docstrings) should be in Numpydoc format. We don’t plan on using automated tools for these docstrings, and the Numpydoc format is well understood in the scientific Python community.

#### 76.5.3 Keyword argument processing

Matplotlib makes extensive use of **kwargs for pass-through customizations from one function to another. A typical example is in matplotlib.pyplot.text(). The definition of the pylab text function is a simple pass-through to matplotlib.axes.Axes.text():

```python
# in pylab.py
def text(*args, **kwargs):
    ret = gca().text(*args, **kwargs)
    draw_if_interactive()
    return ret
```
text() in simplified form looks like this, i.e., it just passes all args and kwargs on to matplotlib.text.

`Text.__init__()`:

```python
# in axes/_axes.py
def text(self, x, y, s, fontdict=None, withdash=False, **kwargs):
    t = Text(x=x, y=y, text=s, **kwargs)
```

and `__init__()` (again with liberties for illustration) just passes them on to the `matplotlib.artist.Artist.update()` method:

```python
# in text.py
def __init__(self, x=0, y=0, text='', **kwargs):
    Artist.__init__(self)
    self.update(kwargs)
```

update does the work looking for methods named like `set_property` if `property` is a keyword argument. i.e., no one looks at the keywords, they just get passed through the API to the artist constructor which looks for suitably named methods and calls them with the value.

As a general rule, the use of `**kwargs` should be reserved for pass-through keyword arguments, as in the example above. If all the keyword args are to be used in the function, and not passed on, use the key/value keyword args in the function definition rather than the `**kwargs` idiom.

In some cases, you may want to consume some keys in the local function, and let others pass through. You can pop the ones to be used locally and pass on the rest. For example, in `plot()`, scalex and scaley are local arguments and the rest are passed on as `Line2D()` keyword arguments:

```python
# in axes/_axes.py
def plot(self, *args, **kwargs):
    scalex = kwargs.pop('scalex', True)
    scaley = kwargs.pop('scaley', True)
    if not self._hold: self.cla()
    lines = []
    for line in self._get_lines(*args, **kwargs):
        self.add_line(line)
        lines.append(line)
```

Note: there is a use case when `kwargs` are meant to be used locally in the function (not passed on), but you still need the `**kwargs` idiom. That is when you want to use `*args` to allow variable numbers of non-keyword args. In this case, python will not allow you to use named keyword args after the `*args` usage, so you will be forced to use `**kwargs`. An example is `matplotlib.contour.ContourLabeler.clabel()`:

```python
# in contour.py
def clabel(self, *args, **kwargs):
    fontsize = kwargs.get('fontsize', None)
    inline = kwargs.get('inline', 1)
    self.fmt = kwargs.get('fmt', '%1.3f')
    colors = kwargs.get('colors', None)
    if len(args) == 0:
        levels = self.levels
        indices = range(len(self.levels))
    elif len(args) == 1:
        ...etc...
```
### 76.5.4 Developing a new backend

If you are working on a custom backend, the `backend` setting in `matplotlibrc` *(Customizing matplotlib)* supports an external backend via the `module` directive. If `my_backend.py` is a Matplotlib backend in your `PYTHONPATH`, you can set it on one of several ways:

- **in `matplotlibrc`**:
  ```
  backend : module://my_backend
  ```

- **with the `MPLBACKEND` environment variable**:
  ```
  > export MPLBACKEND="module://my_backend"
  > python simple_plot.py
  ```

- **from the command shell with the `-d` flag**:
  ```
  > python simple_plot.py -dmodule://my_backend
  ```

- **with the `use` directive in your script**:
  ```python
  import matplotlib
  matplotlib.use('module://my_backend')
  ```

### 76.5.5 Writing examples

We have hundreds of examples in subdirectories of `matplotlib/examples`, and these are automatically generated when the website is built to show up both in the examples and gallery sections of the website.

Any sample data that the example uses should be kept small and distributed with Matplotlib in the `lib/matplotlib/mpl-data/sample_data/` directory. Then in your example code you can load it into a file handle with:

```python
import matplotlib.cbook as cbook
fh = cbook.get_sample_data('mydata.dat')
```
Matplotlib has a testing infrastructure based on nose, making it easy to write new tests. The tests are in matplotlib.tests, and customizations to the nose testing infrastructure are in matplotlib.testing. (There is other old testing cruft around, please ignore it while we consolidate our testing to these locations.)

### 77.1 Requirements

The following software is required to run the tests:

- **nose**, version 1.0 or later
- **mock**, when running python versions < 3.3
- **Ghostscript** (to render PDF files)
- **Inkscape** (to render SVG files)

Optionally you can install:

- **coverage** to collect coverage information
- **pep8** to test coding standards

### 77.2 Building matplotlib for image comparison tests

matplotlib’s test suite makes heavy use of image comparison tests, meaning the result of a plot is compared against a known good result. Unfortunately, different versions of FreeType produce differently formed characters, causing these image comparisons to fail. To make them reproducible, matplotlib can be built with a special local copy of FreeType. This is recommended for all matplotlib developers.

Add the following content to a setup.cfg file at the root of the matplotlib source directory:

```ini
[test]
local_freetype = True
tests = True
```

or by setting the MPLLOCALFREETYPE environmental variable to any true value.
77.3 Running the tests

Running the tests is simple. Make sure you have nose installed and run:

```
python tests.py
```

in the root directory of the distribution. The script takes a set of commands, such as:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--pep8</td>
<td>pep8 checks</td>
</tr>
<tr>
<td>--no-pep8</td>
<td>Do not perform pep8 checks</td>
</tr>
<tr>
<td>--no-network</td>
<td>Disable tests that require network access</td>
</tr>
</tbody>
</table>

Additional arguments are passed on to nosetests. See the nose documentation for supported arguments. Some of the more important ones are given here:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--verbose</td>
<td>Be more verbose</td>
</tr>
<tr>
<td>--processes=NUM</td>
<td>Run tests in parallel over NUM processes</td>
</tr>
<tr>
<td>--process-timeout=SECONDS</td>
<td>Set timeout for results from test runner process</td>
</tr>
<tr>
<td>--nocapture</td>
<td>Do not capture stdout</td>
</tr>
</tbody>
</table>

To run a single test from the command line, you can provide a dot-separated path to the module followed by the function separated by a colon, e.g., (this is assuming the test is installed):

```
python tests.py matplotlib.tests.test_simplification:test_clipping
```

If you want to run the full test suite, but want to save wall time try running the tests in parallel:

```
python tests.py --nocapture --nose-verbose --processes=5 --process-timeout=300
```

An alternative implementation that does not look at command line arguments works from within Python is to run the tests from the matplotlib library function `matplotlib.test()`:

```
import matplotlib
matplotlib.test()
```

**Hint:** To run the tests you need to install nose and mock if using python 2.7:

```
pip install nose
pip install mock
```

77.4 Writing a simple test

Many elements of Matplotlib can be tested using standard tests. For example, here is a test from `matplotlib.tests.test_basic`:

```
from nose.tools import assert_equal

def test_simple():
```
Nose determines which functions are tests by searching for functions beginning with “test” in their name.

If the test has side effects that need to be cleaned up, such as creating figures using the pyplot interface, use the @cleanup decorator:

```python
from matplotlib.testing.decorators import cleanup

cleanup
def test_create_figure():
    """
    very simple example test that creates a figure using pyplot.
    """
    fig = figure()
...
```

### 77.5 Writing an image comparison test

Writing an image based test is only slightly more difficult than a simple test. The main consideration is that you must specify the “baseline”, or expected, images in the `image_comparison()` decorator. For example, this test generates a single image and automatically tests it:

```python
import numpy as np
import matplotlib
from matplotlib.testing.decorators import image_comparison
import matplotlib.pyplot as plt

@image_comparison(baseline_images=['spines_axes_positions'],
                  extensions=['.png'])
def test_spines_axes_positions():
    # SF bug 2852168
    fig = plt.figure()
    x = np.linspace(0,2*np.pi,100)
    y = 2*np.sin(x)
    ax = fig.add_subplot(1,1,1)
    ax.set_title('centered spines')
    ax.plot(x,y)
    ax.spines['right'].set_position(('axes',0.1))
    ax.yaxis.set_ticks_position('right')
    ax.spines['top'].set_position(('axes',0.25))
    ax.xaxis.set_ticks_position('top')
    ax.spines['left'].set_color('none')
    ax.spines['bottom'].set_color('none')
```

The first time this test is run, there will be no baseline image to compare against, so the test will fail. Copy the output images (in this case `result_images/test_category/spines_axes_positions.png`) to the
correct subdirectory of baseline_images tree in the source directory (in this case lib/matplotlib/tests/baseline_images/test_category). Put this new file under source code revision control (with git add). When rerunning the tests, they should now pass.

The image_comparison() decorator defaults to generating png, pdf and svg output, but in interest of keeping the size of the library from ballooning we should only include the svg or pdf outputs if the test is explicitly exercising a feature dependent on that backend.

There are two optional keyword arguments to the image_comparison decorator:

- **extensions**: If you only wish to test additional image formats (rather than just png), pass any additional file types in the list of the extensions to test. When copying the new baseline files be sure to only copy the output files, not their conversions to png. For example only copy the files ending in pdf, not in _pdf.png.

- **tol**: This is the image matching tolerance, the default 1e-3. If some variation is expected in the image between runs, this value may be adjusted.

### 77.6 Known failing tests

If you’re writing a test, you may mark it as a known failing test with the knownfailureif() decorator. This allows the test to be added to the test suite and run on the buildbots without causing undue alarm. For example, although the following test will fail, it is an expected failure:

```python
from nose.tools import assert_equal
from matplotlib.testing.decorators import knownfailureif

@knownfailureif(True)
def test_simple_fail():
    "very simple example test that should fail"
    assert_equal(1+1,3)
```

Note that the first argument to the knownfailureif() decorator is a fail condition, which can be a value such as True, False, or ‘indeterminate’, or may be a dynamically evaluated expression.

### 77.7 Creating a new module in matplotlib.tests

We try to keep the tests categorized by the primary module they are testing. For example, the tests related to the mathtext.py module are in test_mathtext.py.

Let’s say you’ve added a new module named whizbang.py and you want to add tests for it in matplotlib.tests.test_whizbang. To add this module to the list of default tests, append its name to default_test_modules in lib/matplotlib/__init__.py.

### 77.8 Using Travis CI

Travis CI is a hosted CI system “in the cloud”.

1886 Chapter 77. Developer’s tips for testing
Travis is configured to receive notifications of new commits to GitHub repos (via GitHub “service hooks”) and to run builds or tests when it sees these new commits. It looks for a YAML file called `.travis.yml` in the root of the repository to see how to test the project.

Travis CI is already enabled for the main matplotlib GitHub repository – for example, see its Travis page. If you want to enable Travis CI for your personal matplotlib GitHub repo, simply enable the repo to use Travis CI in either the Travis CI UI or the GitHub UI (Admin | Service Hooks). For details, see the Travis CI Getting Started page. This generally isn’t necessary, since any pull request submitted against the main matplotlib repository will be tested.

Once this is configured, you can see the Travis CI results at `https://travis-ci.org/your_GitHub_user_name/matplotlib` – here’s an example.

### 77.9 Using tox

Tox is a tool for running tests against multiple Python environments, including multiple versions of Python (e.g., 2.7, 3.4, 3.5) and even different Python implementations altogether (e.g., CPython, PyPy, Jython, etc.)

Testing all versions of Python (2.6, 2.7, 3.*) requires having multiple versions of Python installed on your system and on the PATH. Depending on your operating system, you may want to use your package manager (such as apt-get, yum or MacPorts) to do this.

Tox makes it easy to determine if your working copy introduced any regressions before submitting a pull request. Here’s how to use it:

```bash
$ pip install tox
$ tox
```

You can also run tox on a subset of environments:

```bash
$ tox -e py26,py27
```

Tox processes everything serially so it can take a long time to test several environments. To speed it up, you might try using a new, parallelized version of tox called detox. Give this a try:

```bash
$ pip install -U -i http://pypi.testrun.org detox
$ detox
```

Tox is configured using a file called `tox.ini`. You may need to edit this file if you want to add new environments to test (e.g., py33) or if you want to tweak the dependencies or the way the tests are run. For more info on the `tox.ini` file, see the Tox Configuration Specification.
DEVELOPER’S TIPS FOR DOCUMENTING MATPLOTLIB

78.1 Getting started

The documentation for matplotlib is generated from ReStructured Text using the Sphinx documentation generation tool. Sphinx-1.0 or later and numpydoc 0.4 or later is required.

The documentation sources are found in the doc/ directory in the trunk. To build the users guide in html format, cd into doc/ and do:

```python
python make.py html
```

or:

```bash
./make.py html
```

you can also pass a latex flag to make.py to build a pdf, or pass no arguments to build everything.

The output produced by Sphinx can be configured by editing the conf.py file located in the doc/.

78.2 Organization of matplotlib’s documentation

The actual ReStructured Text files are kept in doc/users, doc/devel, doc/api and doc/faq. The main entry point is doc/index.rst, which pulls in the index.rst file for the users guide, developers guide, api reference, and faqs. The documentation suite is built as a single document in order to make the most effective use of cross referencing, we want to make navigating the Matplotlib documentation as easy as possible.

Additional files can be added to the various guides by including their base file name (the .rst extension is not necessary) in the table of contents. It is also possible to include other documents through the use of an include statement, such as:

```rst
.. include:: ../../TODO
```
78.2.1 docstrings

In addition to the “narrative” documentation described above, matplotlib also defines its API reference documentation in docstrings. For the most part, these are standard Python docstrings, but matplotlib also includes some features to better support documenting getters and setters.

Matplotlib uses artist introspection of docstrings to support properties. All properties that you want to support through `setp` and `getp` should have a `set_property` and `get_property` method in the `Artist` class. Yes, this is not ideal given python properties or enthought traits, but it is a historical legacy for now. The setter methods use the docstring with the `ACCEPTS` token to indicate the type of argument the method accepts. e.g., in `matplotlib.lines.Line2D`:

```python
# in lines.py
def set_linestyle(self, linestyle):
    r""
    Set the linestyle of the line
    ACCEPTS: [ '-.' | '-' | 'steps' | 'None' | '' ]
    ""
```

Since matplotlib uses a lot of pass-through `kwargs`, e.g., in every function that creates a line (`plot()`, `semilogx()`, `semilogy()`, etc...), it can be difficult for the new user to know which `kwargs` are supported. Matplotlib uses a docstring interpolation scheme to support documentation of every function that takes a `**kwargs`. The requirements are:

1. single point of configuration so changes to the properties don’t require multiple docstring edits.
2. as automated as possible so that as properties change, the docs are updated automagically.

The function `matplotlib.artist.kwdoc()` and the decorator `matplotlib.docstring.dedent_interpd()` facilitate this. They combine python string interpolation in the docstring with the matplotlib artist introspection facility that underlies `setp` and `getp`. The `kwdoc` function gives the list of properties as a docstring. In order to use this in another docstring, first update the `matplotlib.docstring.interpd` object, as seen in this example from `matplotlib.lines`:

```python
# in lines.py
docstring.interpd.update(Line2D=artist.kwdoc(Line2D))
```

Then in any function accepting `Line2D` pass-through `kwargs`, e.g., `matplotlib.axes.Axes.plot()`:

```python
# in axes.py
@docstring.dedent_interpd
def plot(self, *args, **kwargs):
    r""
    Some stuff omitted

    The `kwargs` are `Line2D` properties:
    `(Line2D)`s

    `kwargs` scalex and scaley, if defined, are passed on
to autoscale_view to determine whether the x and y axes are
autoscaled; default True. See `Axes.autoscale_view` for more
    information
    ""
```
Note there is a problem for `Artist__init__` methods, e.g., `matplotlib.patches.Patch.__init__()`, which supports `Patch kwarg`, since the artist inspector cannot work until the class is fully defined and we can’t modify the `Patch__init__.__doc__` docstring outside the class definition. There are some manual hacks in this case, violating the “single entry point” requirement above – see the docstring. `interp.update` calls in `matplotlib.patches`.

### 78.3 Formatting

The Sphinx website contains plenty of documentation concerning ReST markup and working with Sphinx in general. Here are a few additional things to keep in mind:

- Please familiarize yourself with the Sphinx directives for inline markup. Matplotlib’s documentation makes heavy use of cross-referencing and other semantic markup. For example, when referring to external files, use the `:file:` directive.

- Function arguments and keywords should be referred to using the `emphasis` role. This will keep matplotlib’s documentation consistent with Python’s documentation:

  **Here is a description of *argument***

  Please do not use the `default role`:

  Please do not describe `argument` like this.

  nor the `literal role`:

  Please do not describe `'argument` like this.

- Sphinx does not support tables with column- or row-spanning cells for latex output. Such tables can not be used when documenting matplotlib.

- Mathematical expressions can be rendered as png images in html, and in the usual way by latex. For example:

  :math:`\sin(x_n^2)` yields: \( \sin(x_n^2) \), and:

  ::

  .. math::

     \int_{-\infty}^{\infty} \frac{e^{i\phi}}{1+x^2} \frac{e^{i\phi}}{1+x^2}

  yields:

  \[
  \int_{-\infty}^{\infty} \frac{e^{i\phi}}{1+x^2} \frac{e^{i\phi}}{1+x^2}
  \]

- Interactive IPython sessions can be illustrated in the documentation using the following directive:
which would yield:

```
In [69]: lines = plot([1,2,3])
```

- Footnotes\(^1\) can be added using `[#]_`, followed later by:

```
.. rubric:: Footnotes
   .. [#]
```

- Use the `note` and `warning` directives, sparingly, to draw attention to important comments:

```
.. note::
    Here *is* a note
```

  yields:

  **Note:** here is a note

  also:

  **Warning:** here is a warning

- Use the `deprecated` directive when appropriate:

```
.. deprecated:: 0.98
    This feature *is* obsolete, use something **else**.
```

  yields:

  Deprecated since version 0.98: This feature is obsolete, use something else.

- Use the `versionadded` and `versionchanged` directives, which have similar syntax to the `deprecated` role:

```
.. versionadded:: 0.98
    The transforms have been completely revamped.
```

  New in version 0.98: The transforms have been completely revamped.

- Use the `seealso` directive, for example:

\(^1\) For example.
.. seealso::

    Using ReST :ref:`emacs-helpers`:
    One example

    A bit about :ref:`referring-to-mpl-docs`:
    One more

yields:

See also:

**Using ReST Emacs helpers:** One example

**A bit about Referring to mpl documents:** One more

- Please keep the *Glossary* in mind when writing documentation. You can create a references to a term in the glossary with the :term: role.

- The autodoc extension will handle index entries for the API, but additional entries in the index need to be explicitly added.

- Please limit the text width of docstrings to 70 characters.

- Keyword arguments should be described using a definition list.

---

**Note:** matplotlib makes extensive use of keyword arguments as pass-through arguments, there are a many cases where a table is used in place of a definition list for autogenerated sections of docstrings.

## 78.4 Figures

### 78.4.1 Dynamically generated figures

Figures can be automatically generated from scripts and included in the docs. It is not necessary to explicitly save the figure in the script, this will be done automatically at build time to ensure that the code that is included runs and produces the advertised figure.

The path should be relative to the doc directory. Any plots specific to the documentation should be added to the doc/mpl_examples/pyplots directory and committed to git. Plots from the examples directory may be referenced through the symlink mpl_examples in the doc directory. e.g.:

```
.. plot:: mpl_examples/pylab_examples/simple_plot.py
```

The :scale: directive rescales the image to some percentage of the original size, though we don’t recommend using this in most cases since it is probably better to choose the correct figure size and dpi in mpl and let it handle the scaling.
Plot directive documentation

A directive for including a matplotlib plot in a Sphinx document.

By default, in HTML output, `plot` will include a .png file with a link to a high-res .png and .pdf. In LaTeX output, it will include a .pdf.

The source code for the plot may be included in one of three ways:

1. **A path to a source file** as the argument to the directive:

   ```
   .. plot:: path/to/plot.py
   
   When a path to a source file is given, the content of the directive may optionally contain a caption for the plot:
   
   ```
   .. plot:: path/to/plot.py
   
   This is the caption for the plot
   ```

   Additionally, one may specify the name of a function to call (with no arguments) immediately after importing the module:

   ```
   .. plot:: path/to/plot.py plot_function1
   ```

2. Included as **inline content** to the directive:

   ```
   .. plot::
      :import: matplotlib.pyplot as plt
      :import: matplotlib.image as mpimg
      :import: numpy as np
      
      img = mpimg.imread('_static/stinkbug.png')
      imgplot = plt.imshow(img)
   ```

3. Using **doctest** syntax:

   ```
   .. plot::
      :import: matplotlib.pyplot as plt
      :import: matplotlib.image as mpimg
      :import: numpy as np
      
      img = mpimg.imread('_static/stinkbug.png')
      imgplot = plt.imshow(img)
   ```

Options

The `plot` directive supports the following options:

- **format** [{‘python’, ‘doctest’}] Specify the format of the input
- **include-source** [bool] Whether to display the source code. The default can be changed using the `plot_include_source` variable in `conf.py`
**encoding**  [str] If this source file is in a non-UTF8 or non-ASCII encoding, the encoding must be specified using the :encoding: option. The encoding will not be inferred using the -*- coding -*- metacomment.

**context**  [bool or str] If provided, the code will be run in the context of all previous plot directives for which the :context: option was specified. This only applies to inline code plot directives, not those run from files. If the :context: reset option is specified, the context is reset for this and future plots, and previous figures are closed prior to running the code. :context:close-figs keeps the context but closes previous figures before running the code.

**nofigs**  [bool] If specified, the code block will be run, but no figures will be inserted. This is usually useful with the :context: option.

Additionally, this directive supports all of the options of the image directive, except for target (since plot will add its own target). These include alt, height, width, scale, align and class.

### Configuration options

The plot directive has the following configuration options:

- **plot_include_source**  Default value for the include-source option
- **plot_html_show_source_link**  Whether to show a link to the source in HTML.
- **plot_pre_code**  Code that should be executed before each plot.
- **plot_basedir**  Base directory, to which plot:: file names are relative to. (If None or empty, file names are relative to the directory where the file containing the directive is.)
- **plot_formats**  File formats to generate. List of tuples or strings:

```python
[(suffix, dpi), suffix, ...]
```

that determine the file format and the DPI. For entries whose DPI was omitted, sensible defaults are chosen. When passing from the command line through sphinx_build the list should be passed as suffix:dpi,suffix:dpi, ....

- **plot_html_show_formats**  Whether to show links to the files in HTML.
- **plot_rcparams**  A dictionary containing any non-standard rcParams that should be applied before each plot.
- **plot_apply_rcparams**  By default, rcParams are applied when context option is not used in a plot directive. This configuration option overrides this behavior and applies rcParams before each plot.
- **plot_working_directory**  By default, the working directory will be changed to the directory of the example, so the code can get at its data files, if any. Also its path will be added to sys.path so it can import any helper modules sitting beside it. This configuration option can be used to specify a central directory (also added to sys.path) where data files and helper modules for all code are located.
- **plot_template**  Provide a customized template for preparing restructured text.
78.4.2 Static figures

Any figures that rely on optional system configurations need to be handled a little differently. These figures are not to be generated during the documentation build, in order to keep the prerequisites to the documentation effort as low as possible. Please run the doc/pyplots/make.py script when adding such figures, and commit the script and the images to git. Please also add a line to the README in doc/pyplots for any additional requirements necessary to generate a new figure. Once these steps have been taken, these figures can be included in the usual way:

```bash
.. plot:: mpl_examples/pyplots/tex_unicode_demo.py
   :include-source:
```

78.4.3 Examples

The source of the files in the examples directory are automatically included in the HTML docs. An image is generated and included for all examples in the api and pylab_examples directories. To exclude the example from having an image rendered, insert the following special comment anywhere in the script:

```python
# -*- noplot -*-
```

78.4.4 Animations

We have a matplotlib google/gmail account with username mplgithub which we used to setup the github account but can be used for other purposes, like hosting google docs or youtube videos. You can embed a matplotlib animation in the docs by first saving the animation as a movie using `matplotlib.animation.Animation.save()`, and then uploading to matplotlib’s youtube channel and inserting the embedding string youtube provides like:

```html
.. raw:: html
    <iframe width="420" height="315"
    src="http://www.youtube.com/embed/32cjc6V00ZY"
    frameborder="0" allowfullscreen>
</iframe>
```

An example save command to generate a movie looks like this

```python
ani = animation.FuncAnimation(fig, animate, np.arange(1, len(y)),
   interval=25, blit=True, init_func=init)
ani.save('double_pendulum.mp4', fps=15)
```

Contact Michael Droettboom for the login password to upload youtube videos of google docs to the mplgithub account.
78.5 Referring to mpl documents

In the documentation, you may want to include to a document in the matplotlib src, e.g., a license file or an image file from mpl-data, refer to it via a relative path from the document where the rst file resides, e.g., in users/navigation_toolbar.rst, we refer to the image icons with:

.. image:: ../lib/matplotlib/mpl-data/images/subplots.png

In the users subdirectory, if I want to refer to a file in the mpl-data directory, I use the symlink directory. For example, from customizing.rst:

.. literalinclude:: ../lib/matplotlib/mpl-data/matplotlibrc

One exception to this is when referring to the examples dir. Relative paths are extremely confusing in the sphinx plot extensions, so without getting into the dirty details, it is easier to simply include a symlink to the files at the top doc level directory. This way, API documents like matplotlib.pyplot.plot() can refer to the examples in a known location.

In the top level doc directory we have symlinks pointing to the mpl examples:

```
home:~/mpl/doc> ls -l mpl_*
mpl_examples -> ../examples
```

So we can include plots from the examples dir using the symlink:

.. plot:: mpl_examples/pylab_examples/simple_plot.py

We used to use a symlink for mpl-data too, but the distro becomes very large on platforms that do not support links (e.g., the font files are duplicated and large)

78.6 Internal section references

To maximize internal consistency in section labeling and references, use hyphen separated, descriptive labels for section references, e.g.:

.. _howto-webapp:

and refer to it using the standard reference syntax:

```
See :ref:`howto-webapp`
```

Keep in mind that we may want to reorganize the contents later, so let’s avoid top level names in references like user or devel or faq unless necessary, because for example the FAQ “what is a backend?” could later become part of the users guide, so the label:

.. _what-is-a-backend

is better than:
In addition, since underscores are widely used by Sphinx itself, let’s prefer hyphens to separate words.

### 78.7 Section names, etc

For everything but top level chapters, please use **Upper lower** for section titles, e.g., Possible hangups rather than Possible Hangups

### 78.8 Inheritance diagrams

Class inheritance diagrams can be generated with the `inheritance-diagram` directive. To use it, you provide the directive with a number of class or module names (separated by whitespace). If a module name is provided, all classes in that module will be used. All of the ancestors of these classes will be included in the inheritance diagram.

A single option is available: `parts` controls how many of parts in the path to the class are shown. For example, if `parts == 1`, the class `matplotlib.patches.Patch` is shown as Patch. If `parts == 2`, it is shown as `patches.Patch`. If `parts == 0`, the full path is shown.

Example:

```bash
.. inheritance-diagram:: matplotlib.patches matplotlib.lines matplotlib.text
   :parts: 2
```
78.9 Emacs helpers

There is an emacs mode `rst.el` which automates many important ReST tasks like building and updating table-of-contents, and promoting or demoting section headings. Here is the basic `.emacs` configuration:

```(require 'rst)
(setq auto-mode-alist
  (append '(("\.txt$" . rst-mode)
           "\.rst$" . rst-mode)
           ("\.rest$" . rst-mode)) auto-mode-alist))
```

Some helpful functions:

- `C-c TAB - rst-toc-insert`
  
  Insert table of contents at point
- `C-c C-u - rst-toc-update`
<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>C-c C-l rst-shift-region-left</td>
<td>Shift region to the left</td>
</tr>
<tr>
<td>C-c C-r rst-shift-region-right</td>
<td>Shift region to the right</td>
</tr>
</tbody>
</table>

Update the table of contents at point
Matplotlib supports the addition of custom procedures that transform the data before it is displayed.

There is an important distinction between two kinds of transformations. Separable transformations, working on a single dimension, are called “scales”, and non-separable transformations, that handle data in two or more dimensions at a time, are called “projections”.

From the user’s perspective, the scale of a plot can be set with `set_xscale()` and `set_yscale()`. Projections can be chosen using the `projection` keyword argument to the `plot()` or `subplot()` functions, e.g.:

```python
plot(x, y, projection="custom")
```

This document is intended for developers and advanced users who need to create new scales and projections for matplotlib. The necessary code for scales and projections can be included anywhere: directly within a plot script, in third-party code, or in the matplotlib source tree itself.

### 79.1 Creating a new scale

Adding a new scale consists of defining a subclass of `matplotlib.scale.ScaleBase`, that includes the following elements:

- A transformation from data coordinates into display coordinates.
- An inverse of that transformation. This is used, for example, to convert mouse positions from screen space back into data space.
- A function to limit the range of the axis to acceptable values (`limit_range_for_scale()`). A log scale, for instance, would prevent the range from including values less than or equal to zero.
- Locators (major and minor) that determine where to place ticks in the plot, and optionally, how to adjust the limits of the plot to some “good” values. Unlike `limit_range_for_scale()`, which is always enforced, the range setting here is only used when automatically setting the range of the plot.
- Formatters (major and minor) that specify how the tick labels should be drawn.

Once the class is defined, it must be registered with matplotlib so that the user can select it.
A full-fledged and heavily annotated example is in examples/api/custom_scale_example.py. There are also some classes in `matplotlib.scale` that may be used as starting points.

### 79.2 Creating a new projection

Adding a new projection consists of defining a projection axes which subclasses `matplotlib.axes.Axes` and includes the following elements:

- A transformation from data coordinates into display coordinates.
- An inverse of that transformation. This is used, for example, to convert mouse positions from screen space back into data space.
- Transformations for the gridlines, ticks and ticklabels. Custom projections will often need to place these elements in special locations, and matplotlib has a facility to help with doing so.
- Setting up default values (overriding `cla()`), since the defaults for a rectilinear axes may not be appropriate.
- Defining the shape of the axes, for example, an elliptical axes, that will be used to draw the background of the plot and for clipping any data elements.
- Defining custom locators and formatters for the projection. For example, in a geographic projection, it may be more convenient to display the grid in degrees, even if the data is in radians.
- Set up interactive panning and zooming. This is left as an “advanced” feature left to the reader, but there is an example of this for polar plots in `matplotlib.projections.polar`.
- Any additional methods for additional convenience or features.

Once the projection axes is defined, it can be used in one of two ways:

- By defining the class attribute `name`, the projection axes can be registered with `matplotlib.projections.register_projection()` and subsequently simply invoked by name:

```python
plt.axes(projection='my_proj_name')
```

- For more complex, parameterisable projections, a generic “projection” object may be defined which includes the method `_as_mpl_axes`. `_as_mpl_axes` should take no arguments and return the projection's axes subclass and a dictionary of additional arguments to pass to the subclass’ `__init__` method. Subsequently a parameterised projection can be initialised with:

```python
plt.axes(projection=MyProjection(param1=param1_value))
```

where `MyProjection` is an object which implements a `_as_mpl_axes` method.

A full-fledged and heavily annotated example is in examples/api/custom_projection_example.py. The polar plot functionality in `matplotlib.projections.polar` may also be of interest.
79.3 API documentation

- `matplotlib.scale`
- `matplotlib.projections`
- `matplotlib.projections.polar`
As of matplotlib 1.4, the six library is used to support Python 2 and 3 from a single code base. The 2to3 tool is no longer used.

This document describes some of the issues with that approach and some recommended solutions. It is not a complete guide to Python 2 and 3 compatibility.

80.1 Welcome to the __future__

The top of every py file should include the following:

```python
from __future__ import (absolute_import, division,
                        print_function, unicode_literals)
import six
```

This will make the Python 2 interpreter behave as close to Python 3 as possible.

All matplotlib files should also import six, whether they are using it or not, just to make moving code between modules easier, as six gets used a lot.

80.2 Finding places to use six

The only way to make sure code works on both Python 2 and 3 is to make sure it is covered by unit tests. However, the 2to3 commandline tool can also be used to locate places that require special handling with six.

(The modernize tool may also be handy, though I’ve never used it personally).

The six documentation serves as a good reference for the sorts of things that need to be updated.

80.3 The dreaded \\u escapes

When from __future__ import unicode_literals is used, all string literals (not preceded with a b) will become unicode literals.
Normally, one would use “raw” string literals to encode strings that contain a lot of slashes that we don’t want Python to interpret as special characters. A common example in matplotlib is when it deals with TeX and has to represent things like r'"\usepackage{foo}". Unfortunately, on Python 2 there is no way to represent u in a raw unicode string literal, since it will always be interpreted as the start of a unicode character escape, such as u20af. The only solution is to use a regular (non-raw) string literal and repeat all slashes, e.g. "\"\usepackage{foo}".

The following shows the problem on Python 2:

```python
>>> ur'\u'
    File "<stdin>", line 1
SyntaxError: (unicode error) 'rawunicodeescape' codec can't decode bytes in position 0-1: truncated \uXXXX
>>> ur'\\u'
u'\\u'
>>> u'\\u'
    File "<stdin>", line 1
SyntaxError: (unicode error) 'unicodeescape' codec can't decode bytes in position 0-1: truncated \uXXXX escape
>>> u'\\u'
u'\\u'
```

This bug has been fixed in Python 3, however, we can’t take advantage of that and still support Python 2:

```python
>>> r'\u'
'\\u'
>>> r'\\u'
'\\u'
>>> 'u'
    File "<stdin>", line 1
SyntaxError: (unicode error) 'unicodeescape' codec can't decode bytes in position 0-1: truncated \uXXXX escape
>>> '\u'
'\\u'
```

### 80.4 Iteration

The behavior of the methods for iterating over the items, values and keys of a dictionary has changed in Python 3. Additionally, other built-in functions such as zip, range and map have changed to return iterators rather than temporary lists.

In many cases, the performance implications of iterating vs. creating a temporary list won’t matter, so it’s tempting to use the form that is simplest to read. However, that results in code that behaves differently on Python 2 and 3, leading to subtle bugs that may not be detected by the regression tests. Therefore, unless the loop in question is provably simple and doesn’t call into other code, the six versions that ensure the same behavior on both Python 2 and 3 should be used. The following table shows the mapping of equivalent semantics between Python 2, 3 and six for dict.items():
When specifying dtypes, all strings must be byte strings on Python 2 and unicode strings on Python 3. The best way to handle this is to force cast them using \texttt{str()}. The same is true of structure specifiers in the \texttt{struct} built-in module.
WORKING WITH MATPLOTLIB SOURCE CODE

Contents:

81.1 Introduction

These pages describe a git and github workflow for the matplotlib project.
There are several different workflows here, for different ways of working with matplotlib.
This is not a comprehensive git reference, it’s just a workflow for our own project. It’s tailored to the github hosting service. You may well find better or quicker ways of getting stuff done with git, but these should get you started.
For general resources for learning git see git resources.

81.2 Install git

81.2.1 Overview

<table>
<thead>
<tr>
<th>Debian / Ubuntu</th>
<th>sudo apt-get install git-core</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fedora</td>
<td>sudo yum install git-core</td>
</tr>
<tr>
<td>Windows</td>
<td>Download and install msysGit</td>
</tr>
<tr>
<td>OS X</td>
<td>Use the git-osx-installer</td>
</tr>
</tbody>
</table>

81.2.2 In detail

See the git page for the most recent information.
Have a look at the github install help pages available from github help
There are good instructions here: https://git-scm.com/book/en/v2/Getting-Started-Installing-Git
81.3 Following the latest source

These are the instructions if you just want to follow the latest matplotlib source, but you don’t need to do any development for now.

The steps are:

- Install git
- get local copy of the git repository from github
- update local copy from time to time

81.3.1 Get the local copy of the code

From the command line:

```
$ git clone git://github.com/matplotlib/matplotlib.git
```

You now have a copy of the code tree in the new matplotlib directory.

81.3.2 Updating the code

From time to time you may want to pull down the latest code. Do this with:

```
$ cd matplotlib
$ git pull
```

The tree in matplotlib will now have the latest changes from the initial repository.

81.4 Setting up for development

Contents:

81.4.1 Making your own copy (fork) of matplotlib

You need to do this only once. The instructions here are very similar to the instructions at https://help.github.com/forking/ — please see that page for more detail. We’re repeating some of it here just to give the specifics for the matplotlib project, and to suggest some default names.

Set up and configure a github account

If you don’t have a github account, go to the github page, and make one.

You then need to configure your account to allow write access — see the Generating SSH keys help on github help.
Create your own forked copy of matplotlib

1. Log into your github account.
2. Go to the matplotlib github home at matplotlib github.
3. Click on the fork button:

Now, after a short pause you should find yourself at the home page for your own forked copy of matplotlib.

81.4.2 Set up your fork

First you follow the instructions for Making your own copy (fork) of matplotlib.

Overview

```
git clone git@github.com:your-user-name/matplotlib.git
cd matplotlib
git remote add upstream git://github.com/matplotlib/matplotlib.git
```

In detail

Clone your fork

1. Clone your fork to the local computer with `git clone git@github.com:your-user-name/matplotlib.git`
2. Investigate. Change directory to your new repo: `cd matplotlib`. Then `git branch -a` to show you all branches. You’ll get something like:

```
* master
remotes/origin/master
```

This tells you that you are currently on the master branch, and that you also have a remote connection to origin/master. What remote repository is remote/origin? Try `git remote -v` to see the URLs for the remote. They will point to your github fork.

Now you want to connect to the upstream matplotlib github repository, so you can merge in changes from trunk.
Linking your repository to the upstream repo

```bash
cd matplotlib
git remote add upstream git://github.com/matplotlib/matplotlib.git
```

Note that we’ve used `git://` for the URL rather than `git@`. The `git://` URL is read only. This means that we can’t accidentally (or deliberately) write to the upstream repo, and we are only going to use it to merge into our own code.

Just for your own satisfaction, show yourself that you now have a new ‘remote’, with `git remote -v`, giving you something like:

```
upstream  git://github.com/matplotlib/matplotlib.git (fetch)
upstream  git://github.com/matplotlib/matplotlib.git (push)
origin     git@github.com:your-user-name/matplotlib.git (fetch)
origin     git@github.com:your-user-name/matplotlib.git (push)
```

Read-only remote / push access to matplotlib/matplotlib

If you have commit rights to matplotlib/matplotlib the `git://` protocol URL will still be read-only (due to it not supporting authentication and restrictions on github’s side). To reduce the chance of accidentally pushing to upstream, we suggest setting up a read-only remote of upstream as above and a read/write remote as

```bash
git remote add DANGER git@github.com:matplotlib/matplotlib.git
```

or

```bash
git remote add HOLY_COMMIT_RIGHTS_BATMAN https://github.com/matplotlib/matplotlib.git
```

81.4.3 Configure git

Overview

Your personal git configurations are saved in the `.gitconfig` file in your home directory. Here is an example `.gitconfig` file:

```
[user]
    name = Your Name
    email = you@yourdomain.example.com

[alias]
```
ci = commit -a
co = checkout
st = status -a
stat = status -a
br = branch
wdiff = diff --color-words

[core]
editor = vim

[merge]
summary = true

[apply]
whitespace = fix

[core]
autocrlf = input

You can edit this file directly or you can use the `git config --global` command:

```
git config --global user.name "Your Name"
git config --global user.email you@yourdomain.example.com
git config --global alias.ci "commit -a"
git config --global alias.co checkout
git config --global alias.st "status -a"
git config --global alias.stat "status -a"
git config --global alias.br branch
git config --global alias.wdiff "diff --color-words"
git config --global core.editor vim
git config --global merge.summary true
```

To set up on another computer, you can copy your `~/.gitconfig` file, or run the commands above.

**In detail**

**user.name and user.email**

It is good practice to tell git who you are, for labeling any changes you make to the code. The simplest way to do this is from the command line:

```
git config --global user.name "Your Name"
git config --global user.email you@yourdomain.example.com
```

This will write the settings into your git configuration file, which should now contain a user section with your name and email:

```
[user]
  name = Your Name
  email = you@yourdomain.example.com
```
Of course you’ll need to replace Your Name and you@yourdomain.example.com with your actual name and email address.

**Aliases**

You might well benefit from some aliases to common commands.

For example, you might well want to be able to shorten `git checkout` to `git co`. Or you may want to alias `git diff --color-words` (which gives a nicely formatted output of the diff) to `git wdiff`.

The following `git config --global` commands:

```bash
git config --global alias.ci "commit -a"
git config --global alias.co checkout
git config --global alias.st "status -a"
git config --global alias.stat "status -a"
git config --global alias.br branch
git config --global alias.wdiff "diff --color-words"
```

will create an alias section in your `.gitconfig` file with contents like this:

```
[alias]
  ci = commit -a
  co = checkout
  st = status -a
  stat = status -a
  br = branch
  wdiff = diff --color-words
```

**Editor**

You may also want to make sure that your editor of choice is used

```
git config --global core.editor vim
```

**Merging**

To enforce summaries when doing merges (~/.gitconfig file again):

```
[merge]
  log = true
```

Or from the command line:

```
git config --global merge.log true
```
81.4.4 Git Development workflow

You’ve discovered a bug or something else you want to change in matplotlib .. — excellent!
You’ve worked out a way to fix it — even better!
You want to tell us about it — best of all!
The easiest way to contribute to matplotlib is through github. If for some reason you don’t want to use github, see Making patches for instructions on how to email patches to the mailing list.
You already have your own forked copy of the matplotlib repository, by following Making your own copy (fork) of matplotlib, Set up your fork, and you have configured git by following Configure git.

Workflow summary

- Keep your master branch clean of edits that have not been merged to the main matplotlib development repo. Your master then will follow the main matplotlib repository.
- Start a new feature branch for each set of edits that you do.
- Do not merge the master branch or maintenance tracking branches into your feature branch. If you need to include commits from upstream branches (either to pick up a bug fix or to resolve a conflict) please rebase your branch on the upstream branch.
- Ask for review!

This way of working really helps to keep work well organized, and in keeping history as clear as possible.
See — for example — linux git workflow.

Making a new feature branch

```
git checkout -b my-new-feature master
```

This will create and immediately check out a feature branch based on master. To create a feature branch based on a maintenance branch, use:

```
git fetch origin
git checkout -b my-new-feature origin/v1.0.x
```

Generally, you will want to keep this also on your public GitHub fork of matplotlib. To do this, you git push this new branch up to your GitHub repo. Generally (if you followed the instructions in these pages, and by default), git will have a link to your GitHub repo, called origin. You push up to your own repo on GitHub with:

```
git push origin my-new-feature
```

You will need to use this exact command, rather than simply git push every time you want to push changes on your feature branch to your GitHub repo. However, in git >1.7 you can set up a link by using the --set-upstream option:
and then next time you need to push changes to your branch a simple `git push` will suffice. Note that `git push` pushes out all branches that are linked to a remote branch.

### The editing workflow

#### Overview

```
# hack hack
git add my_new_file
git commit -am 'NF - some message'
git push
```

#### In more detail

1. Make some changes

2. See which files have changed with `git status` (see `git status`). You’ll see a listing like this one:

   ```
   # On branch ny-new-feature
   # Changed but not updated:
   # (use "git add <file>..." to update what will be committed)
   # (use "git checkout -- <file>..." to discard changes in working directory)
   #
   # modified:   README
   #
   # Untracked files:
   # (use "git add <file>..." to include in what will be committed)
   #
   # INSTALL
   #
   no changes added to commit (use "git add" and/or "git commit -a")
   ```

3. Check what the actual changes are with `git diff` (see `git diff`).

4. Add any new files to version control `git add new_file_name` (see `git add`).

5. To commit all modified files into the local copy of your repo, do `git commit -am 'A commit message'`. Note the `-am` options to commit. The `m` flag just signals that you’re going to type a message on the command line. The `a` flag — you can just take on faith — or see why the `-a` flag? — and the helpful use-case description in the tangled working copy problem. The `git commit` manual page might also be useful.

6. To push the changes up to your forked repo on GitHub, do a `git push` (see `git push`).

### Asking for code review — open a Pull Request (PR)

It’s a good idea to consult the `Pull request checklist` to make sure your pull request is ready for merging.
1. Go to your repo URL — e.g., https://github.com/your-user-name/matplotlib.

2. Select your feature branch from the drop down menu:

3. Click on the green button:

4. Make sure that you are requesting a pull against the correct branch

5. Enter a PR heading and description (if there is only one commit in the PR github will automatically fill these fields for you). If this PR is addressing a specific issue, please reference it by number (ex #1325) which github will automatically make into links.

6. Click ‘Create Pull Request’ button!

7. Discussion of the change will take place in the pull request thread.

Rebasing a Pull Request (PR)

When working on a PR, changes may occur in the parent branch (usually master). This can lead to conflict with changes in your branch. The conflicts can be trivial: for example both the parent branch and your branch add an entry to the top of CHANGELOG. Git can not unambiguously tell what to do with both changes (should one go above the other? if so, which order? should it try to merge them?) so it declares the branches can not be merged cleanly. GitHub can only automatically merge PR without conflicts, so you will need to manually ‘rebase’. This is the process of updating your branch with upstream changes, and resolving conflicts.

In git, rebasing is a mild form of re-writing history: it effectively forwards all your commits to the updated upstream commit. For a much more detailed explanation (with pictures!) see this nice write up. The NumPy team has also documented how to do this. In general, re-writing history, particularly published history, is considered bad practice, but in this case it is very useful.

The following example assumes that the remote of _your_ GitHub repository is called origin and the remote of the official repository is called matplotlib.

The first step is to make sure that your local copy of the upstream repository is up-to-date:

```
$ git fetch matplotlib
```

This updates your local copy of the repository, but does not change any files in your working copy. Next, switch to the branch that you want to update:

```
$ git checkout backend_plt_refactor
```

You are now ready to start the rebase of your branch onto the target parent branch, in this case matplotlib/master

```
$ git rebase matplotlib/master
```

and git will then give a bunch of feedback:

```
First, rewinding head to replay your work on top of it...
Applying: first steps to extract FigureManager* and friends from pyplot
Applying: split backend_qt4 into two parts, with and without Gcf
```
We see that a number of commits could be cleanly applied to the tip of matplotlib/master. However, git may eventually hit a commit that had conflicts: in the example above, this happens in the file lib/matplotlib/backends/backend_gtk3.py. For more verbose information run

```
$ git status
```

You are currently rebasing branch 'backend_plt_refactor' on 'e6f8993'.
(fix conflicts and then run "git rebase --continue")
(use "git rebase --skip" to skip this patch)
(use "git rebase --abort" to check out the original branch)

Unmerged paths:
(use "git reset HEAD <file>..." to unstage)
(use "git add <file>..." to mark resolution)

    both modified: lib/matplotlib/backends/backend_gtk3.py

no changes added to commit (use "git add" and/or "git commit -a")

This tells you exactly where the conflict (caused by the target branch and your commits modifying the same lines of code) is and provides some advice on how to proceed. Opening up the file in question, you will see blocks that look something like this:

```
<<<<<<< HEAD
=======
    self.__dict__.clear()  # Is this needed? Other backends don't have it.
>>>>>>> pep8 clean up on backend_gtk3.py
```

The block of code between """" and """" is the code on the target branch (in this case nothing) and the code between """" and """" is the code in the commit you are trying to rebase. The rest of the code is either the same or the diff can be unambiguously applied. You need to determine how to resolve the conflict (in this case, the code on HEAD is correct). Once you have resolved all the conflicts, add the file to the index:

```
$ git add lib/matplotlib/backends/backend_gtk3.py
```
Repeat this for all of the files that have conflicts. When you are done with that you can check the status:

```
$ git status
rebase in progress; onto e6f8993
You are currently rebasing branch 'backend_plt_refactor' on 'e6f8993'.
  (all conflicts fixed: run "git rebase --continue")
```

Changes to be committed:
  (use "git reset HEAD <file>..." to unstage)

    modified: lib/matplotlib/backends/backend_gtk3.py

which shows us that we have resolved all of the conflicts with this commit and can continue:

```
$ git rebase --continue
```

You now iterate the until you have made it through all of the commits which have conflicts. Once you have successfully rebased your branch, be sure to re-run the tests to make sure everything is still working properly.

Your branch is now rebased, however, because of the way git determines the hash of each commit, it now shares no commits with your old branch published on GitHub so you can not push to that branch as you would when simply adding commits. In order to publish your newly rebased (and tested!) branch you need to use the `--force` flag:

```
$ git push --force origin
```

which will _replace_ all of the commits under your branch on GitHub with the new versions of the commit. Congratulations, you have rebased your branch!

### Staying up to date with changes in the central repository

This updates your working copy from the upstream matplotlib GitHub repo.

#### Overview

```
# go to your master branch
git checkout master
# pull changes from github
git fetch matplotlib
# merge from matplotlib
git merge --ff-only matplotlib/master
```

#### In detail

We suggest that you do this only for your master branch, and leave your ‘feature’ branches unmerged, to keep their history as clean as possible. This makes code review easier:
Make sure you have done *Linking your repository to the upstream repo*.

Merge the upstream code into your current development by first pulling the upstream repo to a copy on your local machine:

```shell
git fetch upstream
```

then merging into your current branch:

```shell
git merge --ff-only upstream/master
```

The `--ff-only` option guarantees that if you have mistakenly committed code on your `master` branch, the merge fails at this point. If you were to merge `upstream/master` to your `master`, you would start to diverge from the upstream. If this command fails, see the section on *accidents*.

The letters ‘ff’ in `--ff-only` mean ‘fast forward’, which is a special case of merge where git can simply update your branch to point to the other branch and not do any actual merging of files. For `master` and other integration branches this is exactly what you want.

### Other integration branches

Some people like to keep separate local branches corresponding to the maintenance branches on GitHub. At the time of this writing, `v1.0.x` is the active maintenance branch. If you have such a local branch, treat it just as `master`: don’t commit on it, and before starting new branches off of it, update it from upstream:

```shell
git checkout v1.0.x
git fetch upstream
git merge --ff-only upstream/v1.0.x
```

But you don’t necessarily have to have such a branch. Instead, if you are preparing a bugfix that applies to the maintenance branch, fetch from upstream and base your bugfix on the remote branch:

```shell
git fetch upstream

git checkout -b my-<br>bug-fix upstream/v1.0.x
```

### Recovering from accidental commits on master

If you have accidentally committed changes on `master` and `git merge --ff-only` fails, don’t panic! First find out how much you have diverged:

```shell
git diff upstream/master...master
```

If you find that you want simply to get rid of the changes, reset your `master` branch to the upstream version:

```shell
git reset --hard upstream/master
```
As you might surmise from the words ‘reset’ and ‘hard’, this command actually causes your changes to the current branch to be lost, so think twice.

If, on the other hand, you find that you want to preserve the changes, create a feature branch for them:

```
git checkout -b my-important-changes
```

Now `my-important-changes` points to the branch that has your changes, and you can safely reset `master` as above — but make sure to reset the correct branch:

```
git checkout master
git reset --hard upstream/master
```

**Deleting a branch on GitHub**

```
git checkout master
# delete branch locally
git branch -D my-unwanted-branch
# delete branch on GitHub
git push origin :my-unwanted-branch
```

Note the colon : before `my-unwanted-branch`. See also: [https://help.github.com/articles/pushing-to-a-remote/#deleting-a-remote-branch-or-tag](https://help.github.com/articles/pushing-to-a-remote/#deleting-a-remote-branch-or-tag)

**Exploring your repository**

To see a graphical representation of the repository branches and commits:

```
gitk --all
```

To see a linear list of commits for this branch:

```
git log
```

You can also look at the network graph visualizer for your GitHub repo.

**81.4.5 Two and three dots in difference specs**

Thanks to Yarik Halchenko for this explanation.

Imagine a series of commits A, B, C, D... Imagine that there are two branches, `topic` and `master`. You branched `topic` off `master` when `master` was at commit ‘E’. The graph of the commits looks like this:

```
A---B---C topic
  /
D---E---F---G master
```

Then:
will output the difference from G to C (i.e. with effects of F and G), while:

```
git diff master...topic
```

would output just differences in the topic branch (i.e. only A, B, and C).

## 81.5 git resources

### 81.5.1 Tutorials and summaries

- [github help](https://github.com) has an excellent series of how-to guides.
- [learn.github](https://learn.github.com) has an excellent series of tutorials
- The [pro git book](https://git-scm.com/book) is a good in-depth book on git.
- A [git cheat sheet](https://git-scm.com/docs) is a page giving summaries of common commands.
- [The git user manual](https://git-scm.com/docs)
- [The git tutorial](https://git-scm.com/docs)
- [The git community book](https://git-scm.com/docs)
- [git ready](https://git-scm.com/docs) — a nice series of tutorials
- [git casts](https://git-scm.com/docs) — video snippets giving git how-tos.
- [git magic](https://git-scm.com/docs) — extended introduction with intermediate detail
- The [git parable](https://git-scm.com/docs) is an easy read explaining the concepts behind git.
- Our own [git foundation expands on the git parable](https://git-scm.com/docs).
- [Fernando Perez’ git page](https://git-scm.com/docs) — [Fernando’s git page](https://git-scm.com/docs) — many links and tips
- A good but technical page on [git concepts](https://git-scm.com/docs)
- [git svn crash course: git for those of us used to subversion](https://git-scm.com/docs)

### 81.5.2 Advanced git workflow

There are many ways of working with git; here are some posts on the rules of thumb that other projects have come up with:

- Linus Torvalds on [linux git workflow](https://git-scm.com/docs). Summary; use the git tools to make the history of your edits as clean as possible; merge from upstream edits as little as possible in branches where you are doing active development.
81.5.3 Manual pages online

You can get these on your own machine with (e.g) `git help push` or (same thing) `git push --help`, but, for convenience, here are the online manual pages for some common commands:

- `git add`
- `git branch`
- `git checkout`
- `git clone`
- `git commit`
- `git config`
- `git diff`
- `git log`
- `git pull`
- `git push`
- `git remote`
- `git status`

81.6 Making a patch

81.6.1 Making patches

Overview

```bash
# tell git who you are
git config --global user.email you@yourdomain.example.com
git config --global user.name "Your Name Comes Here"
# get the repository if you don't have it
git clone git://github.com/matplotlib/matplotlib.git
# make a branch for your patching
cd matplotlib
git branch the-fix-im-thinking-of
git checkout the-fix-im-thinking-of
# hack, hack, hack
# Tell git about any new files you've made
git add somewhere/tests/test_my_bug.py
# commit work in progress as you go
git commit -am 'BF - added tests for Funny bug'
# hack hack, hack
# make the patch files
# commit -am 'BF - added fix for Funny bug'
git format-patch -M -C master
```
Matplotlib, Release 2.0.0

Then, send the generated patch files to the matplotlib mailing list — where we will thank you warmly.

In detail

1. Tell git who you are so it can label the commits you’ve made:

   ```
git config --global user.email you@yourdomain.example.com
git config --global user.name "Your Name Comes Here"
   ```

2. If you don’t already have one, clone a copy of the matplotlib repository:

   ```
git clone git://github.com/matplotlib/matplotlib.git
cd matplotlib
   ```

3. Make a ‘feature branch’. This will be where you work on your bug fix. It’s nice and safe and leaves you with access to an unmodified copy of the code in the main branch:

   ```
git branch the-fix-im-thinking-of
git checkout the-fix-im-thinking-of
   ```

4. Do some edits, and commit them as you go:

   ```
# hack, hack, hack
# Tell git about any new files you've made
git add somewhere/tests/test_my_bug.py
# commit work in progress as you go
git commit -am 'BF - added tests for Funny bug'
# hack hack, hack
git commit -am 'BF - added fix for Funny bug'
   ```

   Note the -am options to commit. The m flag just signals that you’re going to type a message on the command line. The a flag — you can just take on faith — or see why the -a flag?

5. When you have finished, check you have committed all your changes:

   ```
git status
   ```

6. Finally, make your commits into patches. You want all the commits since you branched from the master branch:

   ```
git format-patch -M -C master
   ```

   You will now have several files named for the commits:

   ```
0001-BF-added-tests-for-Funny-bug.patch
0002-BF-added-fix-for-Funny-bug.patch
   ```

   Send these files to the matplotlib mailing list.

When you are done, to switch back to the main copy of the code, just return to the master branch:
git checkout master
82.1 Pull request checklist

82.1.1 Branch selection

- In general, simple bugfixes that are unlikely to introduce new bugs of their own should be merged onto the maintenance branch. New features, or anything that changes the API, should be made against master. The rules are fuzzy here – when in doubt, target master.

- Once changes are merged into the maintenance branch, they should be merged into master.

82.1.2 Documentation

- Every new feature should be documented. If it’s a new module, don’t forget to add a new rst file to the API docs.

- Each high-level plotting function should have a simple example in the Example section of the docstring. This should be as simple as possible to demonstrate the method. More complex examples should go in the examples tree.

- Build the docs and make sure all formatting warnings are addressed.

- See Developer’s tips for documenting matplotlib for our documentation style guide.

- If your changes are non-trivial, please make an entry in the CHANGESLOG.

- If your change is a major new feature, add an entry to doc/users/whats_new.rst.

- If you change the API in a backward-incompatible way, please document it in doc/api/api_changes.rst.

82.2 PR Review guidelines

- If you have a commit bit, then you are trusted to use it. Please help review and merge PRs!

- Two developers (those with commit rights) should review all pull requests. If you are the first to review a PR please and approve of the changes please edit the title to include '^[MRG+1]' and use the github ‘approve review’ tool to mark it as such. If you are a subsequent reviewer and you approve
either merge (and backport if needed) or increment the number in the title to ask for further review (and trigger the gh ‘approve review’). If you do the merge please removed the ' [MRG+N ]' prefix.

- Make sure the Travis tests are passing before merging.
  - The Travis tests automatically test on all of the Python versions Matplotlib supports whenever a pull request is created or updated. The tox support in Matplotlib may be useful for testing locally.

- Do not self merge, except for ‘small’ patches to un-break the CI.

- Squashing is case-by-case. The balance is between burden on the contributor, keeping a relatively clean history, and keeping a history usable for bisecting. The only time we are really strict about it is to eliminate binary files (ex multiple test image re-generations) and to remove upstream merges.

- Be patient with new contributors.

- Do not let perfect be the enemy of the good, particularly for documentation or example PRs. If you find yourself making many small suggestions, either open a PR against the original branch or merge the PR and then open a new PR against upstream.

### 82.3 Backports

When doing backports please include the branch you backported the commit to along with the SHA in a comment on the original PR.

Assuming we have matplotlib as a read-only remote to the matplotlib/matplotlib repo and DANGER as a read/write remote to the matplotlib/matplotlib repo, we do a backport from master to 2.x. The TARGET_SHA is the hash of the merge commit you would like to backport. This can be read off of the github PR page (in the UI with the merge notification) or through the git CLI tools:

```bash
git fetch matplotlib
git checkout v2.x
git merge --ff-only matplotlib/v2.x
git cherry-pick -m 1 TARGET_SHA
gitk  # to look at it
# local tests? (use your judgment)
git push DANGER v2.x
# leave a comment on PR noting sha of the resulting commit
# from the cherry-pick + branch it was moved to
```

These commands work on git 2.7.1.
A guide for developers who are doing a matplotlib release.

83.1 All Releases

83.1.1 Testing

We use travis-ci for continuous integration. When preparing for a release, the final tagged commit should be tested locally before it is uploaded:

```
python tests.py --processes=8 --process-timeout=300
```

In addition the following two tests should be run and manually inspected:

```
pushd examples/tests/
python backend_driver.py
popd
```

83.1.2 GitHub Stats

We automatically extract GitHub issue, PRs, and authors from GitHub via the API:

```
python tools/github_stats.py --since-tag $TAG --project 'matplotlib/matplotlib' --links > doc/users/github_stats.rst
```

Review and commit changes. Some issue/PR titles may not be valid rst (the most common issue is * which is interpreted as unclosed markup).

83.1.3 Check Docs

Before tagging, make sure that the docs build cleanly
After the docs are built, check that all of the links, internal and external, are still valid. We use linkchecker for this, which has not been ported to python3 yet. You will need to create a python2 environment with requests==2.9.0 and linkchecker

```
conda create -p /tmp/lnkchk python=2 requests==2.9.0
source activate /tmp/lnkchk
pip install linkchecker
pushd doc/build/html
linkchecker index.html --check-extern
```

Address any issues which may arise. The internal links are checked on travis, this should only flag failed external links.

### 83.1.4 Create release commit and tag

To create the tag, first create an empty commit with a very terse set of the release notes in the commit message

```
git commit --allow-empty
```

and then create a signed, annotated tag with the same text in the body message

```
git tag -a -s v2.0.0
```

which will prompt you for your gpg key password and an annotation. For pre releases it is important to follow PEP 440 so that the build artifacts will sort correctly in pypi. Finally, push the tag to GitHub

```
git push -t DANGER v2.0.0
```

Congratulations, the scariest part is done!

To prevent issues with any down-stream builders which download the tarball from GitHub it is important to move all branches away from the commit with the tag\(^1\):

```
git commit --allow-empty
git push DANGER master
```

If this is a final release, also create a ‘doc’ branch (this is not done for pre-releases):

\(^1\) The tarball that is provided by GitHub is produced using `git archive`. We use `versioneer` which uses a format string in `lib/matplotlib/_version.py` to have `git` insert a list of references to exported commit (see `.gitattributes` for the configuration). This string is then used by `versioneer` to produce the correct version, based on the git tag, when users install from the tarball. However, if there is a branch pointed at the tagged commit, then the branch name will also be included in the tarball. When the branch eventually moves, anyone who checked the hash of the tarball before the branch moved will have an incorrect hash.

```
git archive v2.0.0 -o matplotlib-2.0.0.tar.gz --prefix=matplotlib-2.0.0/
```
and if this is a major or minor release, also create a bug-fix branch (a micro release will be cut off of this branch):

```
git branch v2.0.x
git push DANGER v2.0.x
```

### 83.1.5 Release Management / DOI

Via the GitHub UI (chase down link), turn the newly pushed tag into a release. If this is a pre-release remember to mark it as such.

For final releases also get a DOI from [zenodo](https://zenodo.org) and edit `doc/_templates/citing.html` with DOI link and commit to the VER-doc branch and push to GitHub

```
git checkout v2.0.0-doc
emacs doc/_templates/citing.html
git push DANGER v2.0.0-doc:v2.0.0-doc
```

### 83.1.6 Building binaries

We distribute mac, windows, and many linux wheels as well as a source tarball via pypi. Before uploading anything, contact the various builders. Mac and manylinux wheels are built on travis. You need to edit the `.travis.yml` file and push to master of the build project.

Update the master branch (for pre-releases the devel branch) of the [conda-forge feedstock](https://conda-forge.github.io) via pull request.

If this is a final release the following downstream packagers should be contacted:

- Debian
- Fedora
- Arch
- Gentoo
- Macports
- Homebrew
- Christoph Gohlke
- Continuum
- Enthought

This can be done ahead of collecting all of the binaries and uploading to pypi.
83.1.7 make distribution and upload to pypi / SF

Once you have collected all of the wheels, generate the tarball

```bash
git checkout v2.0.0
git clean -xfd
python setup.py sdist
```

and copy all of the wheels into `dist` directory. You should use `twine` to upload all of the files to pypi

```bash
twine upload -s dist/matplotlib.tar.gz
twine upload dist/*whl
```

Congratulations, you have now done the second scariest part!

Additionally, for a final release, upload all of the files to sourceforge.

83.1.8 Build and Deploy Documentation

To build the documentation you must have the tagged version installed, but build the docs from the `ver-doc` branch. An easy way to arrange this is:

```bash
pip install matplotlib
pip install -r doc-requirements.txt
git checkout v2.0.0-doc
git clean -xfd
cd doc
python make.py html latex -n 16
```

which will build both the html and pdf version of the documentation.

The built documentation exists in the `matplotlib.github.com` repository. Pushing changes to master automatically updates the website.

The documentation is organized by version. At the root of the tree is always the documentation for the latest stable release. Under that, there are directories containing the documentation for older versions. The documentation for current master are built on travis and push to the `devdocs` repository. These are available at `matplotlib.org/devdocs`.

Assuming you have this repository checked out in the same directory as `matplotlib`

```bash
cd ../matplotlib.github.com
mkdir 2.0.0
rsync -a ../matplotlib/doc/build/html/* 2.0.0
cp ../matplotlib/doc/build/latex/Matplotlib.pdf 2.0.0
```

which will copy the built docs over. If this is a final release, also replace the top-level docs

```bash
rsync -a 2.0.0/* ./
```

You will need to manually edit `versions.html` to show the last 3 tagged versions. Now commit and push everything to GitHub
git add *
git commit -a -m 'Updating docs for v2.0.0'
git push DANGER master

Congratulations you have now done the third scariest part!

It typically takes about 5-10 minutes for GitHub to process the push and update the live web page (remember to clear your browser cache).

### 83.1.9 Announcing

The final step is to announce the release to the world. A short version of the release notes along with acknowledgments should be sent to

- matplotlib-user@python.org
- matplotlib-devel@python.org
- matplotlib-announce@python.org

For final releases announcements should also be sent to the numpy/scipy/jupyter mailing lists and python-announce.

In addition, announcements should be made on social networks (twitter, g+, FB). For major release, NumFOCUS should be contacted for inclusion in their newsletter and maybe to have something posted on their blog.
84.1 MEP Template

- **Status**
- **Branches and Pull requests**
- **Abstract**
- **Detailed description**
- **Implementation**
- **Backward compatibility**
- **Alternatives**

This MEP template is a guideline of the sections that a MEP should contain. Extra sections may be added if appropriate, and unnecessary sections may be noted as such.

84.1.1 Status

MEPs go through a number of phases in their lifetime:

- **Discussion**: The MEP is being actively discussed on the mailing list and it is being improved by its author. The mailing list discussion of the MEP should include the MEP number (MEPxxx) in the subject line so they can be easily related to the MEP.
- **Progress**: Consensus was reached on the mailing list and implementation work has begun.
- **Completed**: The implementation has been merged into master.
- **Superseded**: This MEP has been abandoned in favor of another approach.

84.1.2 Branches and Pull requests

All development branches containing work on this MEP should be linked to from here.
All pull requests submitted relating to this MEP should be linked to from here. (A MEP does not need to be implemented in a single pull request if it makes sense to implement it in discrete phases).

### 84.1.3 Abstract

The abstract should be a short description of what the MEP will achieve.

### 84.1.4 Detailed description

This section describes the need for the MEP. It should describe the existing problem that it is trying to solve and why this MEP makes the situation better. It should include examples of how the new functionality would be used and perhaps some use cases.

### 84.1.5 Implementation

This section lists the major steps required to implement the MEP. Where possible, it should be noted where one step is dependent on another, and which steps may be optionally omitted. Where it makes sense, each step should include a link related pull requests as the implementation progresses.

### 84.1.6 Backward compatibility

This section describes the ways in which the MEP breaks backward incompatibility.

### 84.1.7 Alternatives

If there were any alternative solutions to solving the same problem, they should be discussed here, along with a justification for the chosen approach.

### 84.2 MEP8: PEP8

- **Status**
- **Branches and Pull requests**
- **Abstract**
- **Detailed description**
- **Implementation**
- **Backward compatibility**
- **Alternatives**
84.2.1 Status

Discussion

84.2.2 Branches and Pull requests

None so far.

84.2.3 Abstract

The matplotlib codebase predates PEP8, and therefore is less than consistent style-wise in some areas. Bringing the codebase into compliance with PEP8 would go a long way to improving its legibility.

84.2.4 Detailed description

Some files use four space indentation, some use three. Some use different levels in the same file.
For the most part, class/function/variable naming follows PEP8, but it wouldn’t hurt to fix where necessary.

84.2.5 Implementation

The implementation should be fairly mechanical: running the pep8 tool over the code and fixing where appropriate.
This should be merged in after the 2.0 release, since the changes will likely make merging any pending pull requests more difficult.
Additionally, and optionally, PEP8 compliance could be tracked by an automated build system.

84.2.6 Backward compatibility

Public names of classes and functions that require change (there shouldn’t be many of these) should first be deprecated and then removed in the next release cycle.

84.2.7 Alternatives

PEP8 is a popular standard for Python code style, blessed by the Python core developers, making any alternatives less desirable.

84.3 MEP9: Global interaction manager
Add a global manager for all user interactivity with artists; make any artist resizeable, moveable, highlightable, and selectable as desired by the user.

### 84.3.1 Status

Discussion

### 84.3.2 Branches and Pull requests

https://github.com/dhyams/matplotlib/tree/MEP9

### 84.3.3 Abstract

The goal is to be able to interact with matplotlib artists in a very similar way as drawing programs do. When appropriate, the user should be able to move, resize, or select an artist that is already on the canvas. Of course, the script writer is ultimately in control of whether an artist is able to be interacted with, or whether it is static.

This code to do this has already been privately implemented and tested, and would need to be migrated from its current "mixin" implementation, to a bona-fide part of matplotlib.

The end result would be to have four new keywords available to matplotlib.artist.Artist: `_moveable_`, `_resizeable_`, `_selectable_`, and `_highlightable_`. Setting any one of these keywords to True would activate interactivity for that artist.

In effect, this MEP is a logical extension of event handling in matplotlib; matplotlib already supports "low level" interactions like left mouse presses, a key press, or similar. The MEP extends the support to the logical level, where callbacks are performed on the artists when certain interactive gestures from the user are detected.
84.3.4 Detailed description

This new functionality would be used to allow the end-user to better interact with the graph. Many times, a graph is almost what the user wants, but a small repositioning and/or resizing of components is necessary. Rather than force the user to go back to the script to trial-and-error the location, and simple drag and drop would be appropriate.

Also, this would better support applications that use matplotlib; here, the end-user has no reasonable access or desire to edit the underlying source in order to fine-tune a plot. Here, if matplotlib offered the capability, one could move or resize artists on the canvas to suit their needs. Also, the user should be able to highlight (with a mouse over) an artist, and select it with a double-click, if the application supports that sort of thing. In this MEP, we also want to support the highlighting and selection natively; it is up to application to handle what happens when the artist is selected. A typical handling would be to display a dialog to edit the properties of the artist.

In the future, as well (this is not part of this MEP), matplotlib could offer backend-specific property dialogs for each artist, which are raised on artist selection. This MEP would be a necessary stepping stone for that sort of capability.

There are currently a few interactive capabilities in matplotlib (e.g. legend.draggable()), but they tend to be scattered and are not available for all artists. This MEP seeks to unify the interactive interface and make it work for all artists.

The current MEP also includes grab handles for resizing artists, and appropriate boxes drawn when artists are moved or resized.

84.3.5 Implementation

- Add appropriate methods to the “tree” of artists so that the interactivity manager has a consistent interface for the interactivity manager to deal with. The proposed methods to add to the artists, if they are to support interactivity, are:
  - get_pixel_position_ll(self): get the pixel position of the lower left corner of the artist’s bounding box
  - get_pixel_size(self): get the size of the artist’s bounding box, in pixels
  - set_pixel_position_and_size(self,x,y,dx,dy): set the new size of the artist, such that it fits within the specified bounding box.
- add capability to the backends to 1) provide cursors, since these are needed for visual indication of moving/resizing, and 2) provide a function that gets the current mouse position
- Implement the manager. This has already been done privately (by dhyams) as a mixin, and has been tested quite a bit. The goal would be to move the functionality of the manager into the artists so that it is in matplotlib properly, and not as a “monkey patch” as I currently have it coded.

84.3.6 Current summary of the mixin

(Note that this mixin is for now just private code, but can be added to a branch obviously)
InteractiveArtistMixin:

Mixin class to make any generic object that is drawn on a matplotlib canvas moveable and possibly resizeable. The Powerpoint model is followed as closely as possible; not because I’m enamoured with Powerpoint, but because that’s what most people understand. An artist can also be selectable, which means that the artist will receive the on_activated() callback when double clicked. Finally, an artist can be highlightable, which means that a highlight is drawn on the artist whenever the mouse passes over. Typically, highlightable artists will also be selectable, but that is left up to the user. So, basically there are four attributes that can be set by the user on a per-artist basis:

- highlightable
- selectable
- moveable
- resizeable

To be moveable (draggable) or resizeable, the object that is the target of the mixin must support the following protocols:

- `get_pixel_position_ll(self)`
- `get_pixel_size(self)`
- `set_pixel_position_and_size(self,x,y,sx,dy)`

Note that nonresizeable objects are free to ignore the sx and sy parameters. To be highlightable, the object that is the target of the mixin must also support the following protocol:

- `get_highlight(self)`

Which returns a list of artists that will be used to draw the highlight.

If the object that is the target of the mixin is not an matplotlib artist, the following protocols must also be implemented. Doing so is usually fairly trivial, as there has to be an artist somewhere that is being drawn. Typically your object would just route these calls to that artist.

- `get_figure(self)`
- `get_axes(self)`
- `contains(self,event)`
- `set_animated(self,flag)`
- `draw(self,renderer)`
- `get_visible(self)`

The following notifications are called on the artist, and the artist can optionally implement these.

- `on_select_begin(self)`
- `on_select_end(self)`
- `on_drag_begin(self)`
- `on_drag_end(self)`
• on_activated(self)
• on_highlight(self)
• on_right_click(self,event)
• on_left_click(self,event)
• on_middle_click(self,event)
• on_context_click(self,event)
• on_key_up(self,event)
• on_key_down(self,event)

The following notifications are called on the canvas, if no interactive artist handles the event:

• on_press(self,event)
• on_left_click(self,event)
• on_middle_click(self,event)
• on_right_click(self,event)
• on_context_click(self,event)
• on_key_up(self,event)
• on_key_down(self,event)

The following functions, if present, can be used to modify the behavior of the interactive object:

• press_filter(self,event) # determines if the object wants to have the press event routed to it
• handle_unpicked_cursor() # can be used by the object to set a cursor as the cursor passes over the object when it is unpicked.

Supports multiple canvases, maintaining a drag lock, motion notifier, and a global “enabled” flag per canvas. Supports fixed aspect ratio resizings by holding the shift key during the resize.

Known problems:

• Zorder is not obeyed during the selection/drag operations. Because of the blit technique used, I do not believe this can be fixed. The only way I can think of is to search for all artists that have a zorder greater than me, set them all to animated, and then redraw them all on top during each drag refresh. This might be very slow; need to try.

• the mixin only works for wx backends because of two things: 1) the cursors are hardcoded, and 2) there is a call to wx.GetMousePosition() Both of these shortcomings are reasonably fixed by having each backend supply these things.

84.3.7 Backward compatibility

No problems with backward compatibility, although once this is in place, it would be appropriate to obsolete some of the existing interactive functions (like legend.draggable())
84.3.8 Alternatives

None that I know of.

84.4 MEP10: Docstring consistency

- Status
- Branches and Pull requests
- Abstract
- Detailed description
  - Numpy docstring format
  - Cross references
  - Overriding signatures
  - Linking rather than duplicating
  - autosummary extension
  - Examples linking to relevant documentation
  - Documentation using help() vs a browser

- Implementation
- Backward compatibility
- Alternatives

84.4.1 Status

Progress
Targeted for 1.3

84.4.2 Branches and Pull requests

#1665 #1757 #1795

84.4.3 Abstract

matplotlib has a great deal of inconsistency between docstrings. This not only makes the docs harder to read, but it is harder on contributors, because they don’t know which specifications to follow. There should be a clear docstring convention that is followed consistently.
The organization of the API documentation is difficult to follow. Some pages, such as pyplot and axes, are enormous and hard to browse. There should instead be short summary tables that link to detailed documentation. In addition, some of the docstrings themselves are quite long and contain redundant information.

Building the documentation takes a long time and uses a `make.py` script rather than a Makefile.

### 84.4.4 Detailed description

There are number of new tools and conventions available since matplotlib started using Sphinx that make life easier. The following is a list of proposed changes to docstrings, most of which involve these new features.

#### Numpy docstring format

Numpy docstring format: This format divides the docstring into clear sections, each having different parsing rules that make the docstring easy to read both as raw text and as HTML. We could consider alternatives, or invent our own, but this is a strong choice, as it’s well used and understood in the Numpy/Scipy community.

#### Cross references

Most of the docstrings in matplotlib use explicit “roles” when linking to other items, for example: `:func:`myfunction`. As of Sphinx 0.4, there is a “default_role” that can be set to “obj”, which will polymorphically link to a Python object of any type. This allows one to write `myfunction` instead. This makes docstrings much easier to read and edit as raw text. Additionally, Sphinx allows for setting a current module, so links like `~matplotlib.axes.Axes.set_xlim` could be written as `~axes.Axes.set_xlim`.

#### Overriding signatures

Many methods in matplotlib use the *args and **kwargs syntax to dynamically handle the keyword arguments that are accepted by the function, or to delegate on to another function. This, however, is often not useful as a signature in the documentation. For this reason, many matplotlib methods include something like:

```python
def annotate(self, *args, **kwargs):
    """
    Create an annotation: a piece of text referring to a data point.

    Call signature:

    annotate(s, xy, xytext=None, xycoords='data',
             textcoords='data', arrowprops=None, **kwargs)
    """
```

This can’t be parsed by Sphinx, and is rather verbose in raw text. As of Sphinx 1.1, if the `autodoc_docstring_signature` config value is set to True, Sphinx will extract a replacement signature from the first line of the docstring, allowing this:

```python
def annotate(self, *args, **kwargs):
    """
    Create an annotation: a piece of text referring to a data point.

    Call signature:

    annotate(s, xy, xytext=None, xycoords='data',
             textcoords='data', arrowprops=None, **kwargs)
    """
```
def annotate(self, *args, **kwargs):
    
    annotate(s, xy, xytext=None, xycoords='data',
             textcoords='data', arrowprops=None, **kwargs)

    Create an annotation: a piece of text referring to a data point.

The explicit signature will replace the actual Python one in the generated documentation.

**Linking rather than duplicating**

Many of the docstrings include long lists of accepted keywords by interpolating things into the docstring at load time. This makes the docstrings very long. Also, since these tables are the same across many docstrings, it inserts a lot of redundant information in the docs – particularly a problem in the printed version.

These tables should be moved to docstrings on functions whose only purpose is for help. The docstrings that refer to these tables should link to them, rather than including them verbatim.

**autosummary extension**

The Sphinx autosummary extension should be used to generate summary tables, that link to separate pages of documentation. Some classes that have many methods (e.g. `Axes.axes`) should be documented with one method per page, whereas smaller classes should have all of their methods together.

**Examples linking to relevant documentation**

The examples, while helpful at illustrating how to use a feature, do not link back to the relevant docstrings. This could be addressed by adding module-level docstrings to the examples, and then including that docstring in the parsed content on the example page. These docstrings could easily include references to any other part of the documentation.

**Documentation using help() vs a browser**

Using Sphinx markup in the source allows for good-looking docs in your browser, but the markup also makes the raw text returned using help() look terrible. One of the aims of improving the docstrings should be to make both methods of accessing the docs look good.

**84.4.5 Implementation**

1. The numpydoc extensions should be turned on for matplotlib. There is an important question as to whether these should be included in the matplotlib source tree, or used as a dependency. Installing Numpy is not sufficient to get the numpydoc extensions – it’s a separate install procedure. In any
case, to the extent that they require customization for our needs, we should endeavor to submit those changes upstream and not fork them.

2. Manually go through all of the docstrings and update them to the new format and conventions. Updating the cross references (from `:func:` `myfunc` to `func`) may be able to be semi-automated. This is a lot of busy work, and perhaps this labor should be divided on a per-module basis so no single developer is over-burdened by it.

3. Reorganize the API docs using autosummary and `sphinx-autogen`. This should hopefully have minimal impact on the narrative documentation.

4. Modify the example page generator (`gen_rst.py`) so that it extracts the module docstring from the example and includes it in a non-literal part of the example page.

5. Use `sphinx-quickstart` to generate a new-style Sphinx Makefile. The following features in the current `make.py` will have to be addressed in some other way:
   - Copying of some static content
   - Specifying a “small” build (only low-resolution PNG files for examples)

Steps 1, 2, and 3 are interdependent. 4 and 5 may be done independently, though 5 has some dependency on 3.

### 84.4.6 Backward compatibility

As this mainly involves docstrings, there should be minimal impact on backward compatibility.

### 84.4.7 Alternatives

None yet discussed.

### 84.5 MEP11: Third-party dependencies
This MEP attempts to improve the way in which third-party dependencies in matplotlib are handled.

### 84.5.1 Status

**Completed** – needs to be merged

### 84.5.2 Branches and Pull requests

- #1157: Use automatic dependency resolution
- #1290: Debundle pyparsing
- #1261: Update six to 1.2

### 84.5.3 Abstract

One of the goals of matplotlib has been to keep it as easy to install as possible. To that end, some third-party dependencies are included in the source tree and, under certain circumstances, installed alongside matplotlib. This MEP aims to resolve some problems with that approach, bring some consistency, while continuing to make installation convenient.

At the time that was initially done, setuptools, easy_install and PyPI were not mature enough to be relied on. However, at present, we should be able to safely leverage the “modern” versions of those tools, distribute and pip.

While matplotlib has dependencies on both Python libraries and C/C++ libraries, this MEP addresses only the Python libraries so as to not confuse the issue. C libraries represent a larger and mostly orthogonal set of problems.

### 84.5.4 Detailed description

matplotlib depends on the following third-party Python libraries:

- Numpy
- dateutil (pure Python)
- pytz (pure Python)
- six – required by dateutil (pure Python)
- pyparsing (pure Python)
- PIL (optional)
- GUI frameworks: pygtk, gobject, tkinter, PySide, PyQt4, wx (all optional, but one is required for an interactive GUI)
Current behavior

When installing from source, a git checkout or pip:

- `setup.py` attempts to import `numpy`. If this fails, the installation fails.
- For each of `dateutil`, `pytz` and `six`, `setup.py` attempts to import them (from the top-level namespace). If that fails, matplotlib installs its local copy of the library into the top-level namespace.
- `pyparsing` is always installed inside of the matplotlib namespace.

This behavior is most surprising when used with pip, because no pip dependency resolution is performed, even though it is likely to work for all of these packages.

The fact that `pyparsing` is installed in the matplotlib namespace has reportedly (#1290) confused some users into thinking it is a matplotlib-related module and import it from there rather than the top-level.

When installing using the Windows installer, `dateutil`, `pytz` and `six` are installed at the top-level *always*, potentially overwriting already installed copies of those libraries.

TODO: Describe behavior with the OS-X installer.

When installing using a package manager (Debian, RedHat, MacPorts etc.), this behavior actually does the right thing, and there are no special patches in the matplotlib packages to deal with the fact that we handle `dateutil`, `pytz` and `six` in this way. However, care should be taken that whatever approach we move to continues to work in that context.

Maintaining these packages in the matplotlib tree and making sure they are up-to-date is a maintenance burden. Advanced new features that may require a third-party pure Python library have a higher barrier to inclusion because of this burden.

Desired behavior

Third-party dependencies are downloaded and installed from their canonical locations by leveraging `pip`, `distribute` and PyPI.

dateutil, pytz, and pyparsing should be made into optional dependencies – though obviously some features would fail if they aren’t installed. This will allow the user to decide whether they want to bother installing a particular feature.

84.5.5 Implementation

For installing from source, and assuming the user has all of the C-level compilers and dependencies, this can be accomplished fairly easily using `distribute` and following the instructions here. The only anticipated change to the matplotlib library code will be to import pyparsing from the top-level namespace rather than from within matplotlib. Note that `distribute` will also allow us to remove the direct dependency on six, since it is, strictly speaking, only a direct dependency of dateutil.

For binary installations, there are a number of alternatives (here ordered from best/hardest to worst/easiest):
1. The distutils wininst installer allows a post-install script to run. It might be possible to get this script to run `pip` to install the other dependencies. (See this thread for someone who has trod that ground before).

2. Continue to ship `dateutil`, `pytz`, `six` and `pyparsing` in our installer, but use the post-install-script to install them *only* if they can not already be found.

3. Move all of these packages inside a (new) `matplotlib.extern` namespace so it is clear for outside users that these are external packages. Add some conditional imports in the core matplotlib codebase so `dateutil` (at the top-level) is tried first, and failing that `matplotlib.extern.dateutil` is used.

2 and 3 are undesirable as they still require maintaining copies of these packages in our tree – and this is exacerbated by the fact that they are used less – only in the binary installers. None of these 3 approaches address Numpy, which will still have to be manually installed using an installer.

TODO: How does this relate to the Mac OS-X installer?

### 84.5.6 Backward compatibility

At present, matplotlib can be installed from source on a machine without the third party dependencies and without an internet connection. After this change, an internet connection (and a working PyPI) will be required to install matplotlib for the first time. (Subsequent matplotlib updates or development work will run without accessing the network).

### 84.5.7 Alternatives

Distributing binary *eggs* doesn’t feel like a usable solution. That requires getting `easy_install` installed first, and Windows users generally prefer the well known `exe` or `msi` installer that works out of the box.

### 84.6 MEP12: Improve Gallery and Examples

- **Status**
- **Branches and Pull requests**
- **Abstract**
- **Detailed description**
- **Implementation**
  - Gallery sections
  - Clean up guidelines
    - Additional suggestions
- **Backward compatibility**
84.6.1 Status

Progress

Initial changes added in 1.3. Conversion of the gallery is on-going. 29 September 2015 - The last pylab_examples where pylab is imported has been converted over to use matplotlib pyplot and numpy.

84.6.2 Branches and Pull requests

#1623, #1924, #2181

PR #2474 <https://github.com/matplotlib/matplotlib/pull/2474> demonstrates a single example being cleaned up and moved to the appropriate section.

84.6.3 Abstract

Reorganizing the matplotlib plot gallery would greatly simplify navigation of the gallery. In addition, examples should be cleaned-up and simplified for clarity.

84.6.4 Detailed description

The matplotlib gallery was recently set up to split examples up into sections. As discussed in that PR\(^1\), the current example sections (api, pylab_examples) aren’t terribly useful to users: New sections in the gallery would help users find relevant examples.

These sections would also guide a cleanup of the examples: Initially, all the current examples would remain and be listed under their current directories. Over time, these examples could be cleaned up and moved into one of the new sections.

This process allows users to easily identify examples that need to be cleaned up; i.e. anything in the api and pylab_examples directories.

84.6.5 Implementation

1. Create new gallery sections. [Done]
2. Clean up examples and move them to the new gallery sections (over the course of many PRs and with the help of many users/developers). [In progress]

\(^1\) https://github.com/matplotlib/matplotlib/pull/714
Gallery sections

The naming of sections is critical and will guide the clean-up effort. The current sections are:

- Lines, bars, and markers (more-or-less 1D data)
- Shapes and collections
- Statistical plots
- Images, contours, and fields
- Pie and polar charts: Round things
- Color
- Text, labels, and annotations
- Ticks and spines
- Subplots, axes, and figures
- Specialty plots (e.g., sankey, radar, tornado)
- Showcase (plots with tweaks to make them publication-quality)
- separate sections for toolboxes (already exists: 'mplot3d', 'axes_grid', 'units', 'widgets')

These names are certainly up for debate. As these sections grow, we should reevaluate them and split them up as necessary.

Clean up guidelines

The current examples in the api and pylab_examples sections of the gallery would remain in those directories until they are cleaned up. After clean-up, they would be moved to one of the new gallery sections described above. “Clean-up” should involve:

- PEP8 clean-ups (running flake8, or a similar checker, is highly recommended)
- Commented-out code should be removed.
- Add introductory sentence or paragraph in the main docstring. See 6d1b8a2.
- Replace uses of pylab interface with pyplot (+ numpy, etc.). See c25e1e
- Remove shebang line, e.g.:
  
  #!/usr/bin/env python

- Use consistent imports. In particular:
  
  import numpy as np
  import matplotlib.pyplot as plt

  Avoid importing specific functions from these modules (e.g. from numpy import sin)
• Each example should focus on a specific feature (excluding showcase examples, which will show more “polished” plots). Tweaking unrelated to that feature should be removed. See f7b2217, e57b5fc, and 1458aa8

Use of `pylab` should be demonstrated/discussed on a dedicated help page instead of the gallery examples.

**Note:** When moving an existing example, you should search for references to that example. For example, the API documentation for `axes.py` and `pyplot.py` may use these examples to generate plots. Use your favorite search tool (e.g., grep, ack, grin, pss) to search the matplotlib package. See 2dc9a46 and aa6b410

### Additional suggestions

• Provide links (both ways) between examples and API docs for the methods/objects used. (issue #2222)

• Use `plt.subplots` (note trailing “s”) in preference over `plt.subplot`.

• Rename the example to clarify it’s purpose. For example, the most basic demo of `imshow` might be `imshow_demo.py`, and one demonstrating different interpolation settings would be `imshow_demo_interpolation.py` (not `imshow_demo2.py`).

• Split up examples that try to do too much. See 5099675 and fc2ab07

• Delete examples that don’t show anything new.

• Some examples exercise esoteric features for unit testing. These tweaks should be moved out of the gallery to an example in the `unit` directory located in the root directory of the package.

• Add plot titles to clarify intent of the example. See bd2b13c

### 84.6.6 Backward compatibility

The website for each Matplotlib version is readily accessible, so users who want to refer to old examples can still do so.

### 84.6.7 Alternatives

#### Tags

Tagging examples will also help users search the example gallery. Although tags would be a big win for users with specific goals, the plot gallery will remain the entry point to these examples, and sections could really help users navigate the gallery. Thus, tags are complementary to this reorganization.

### 84.7 MEP13: Use properties for Artists
84.7.1 Status

• Discussion

84.7.2 Branches and Pull requests

None

84.7.3 Abstract

Wrap all of the matplotlib getter and setter methods with python properties, allowing them to be read and written like class attributes.

84.7.4 Detailed description

Currently matplotlib uses getter and setter functions (usually prefixed with get_ and set_, respectively) for reading and writing data related to classes. However, since 2.6 python supports properties, which allow such setter and getter functions to be accessed as though they were attributes. This proposal would implement all existing setter and getter methods as properties.

84.7.5 Implementation

1. All existing getter and setter methods will need to have two aliases, one with the get_ or set_ prefix and one without. Getter methods that currently lack prefixes should be recording in a text file.
2. Classes should be reorganized so setter and getter methods are sequential in the code, with getter methods first.

3. Getter and setter methods the provide additional optional optional arguments should have those arguments accessible in another manner, either as additional getter or setter methods or attributes of other classes. If those classes are not accessible, getters for them should be added.

4. Property decorators will be added to the setter and getter methods without the prefix. Those with the prefix will be marked as deprecated.

5. Docstrings will need to be rewritten so the getter with the prefix has the current docstring and the getter without the prefix has a generic docstring appropriate for an attribute.

6. Automatic alias generation will need to be modified so it will also create aliases for the properties.

7. All instances of getter and setter method calls will need to be changed to attribute access.

8. All setter and getter aliases with prefixes will be removed

The following steps can be done simultaneously: 1, 2, and 3; 4 and 5; 6 and 7.

Only the following steps must be done in the same release: 4, 5, and 6. All other changes can be done in separate releases. 8 should be done several major releases after everything else.

84.7.6 Backward compatibility

All existing getter methods that do not have a prefix (such as get_) will need to be changed from function calls to attribute access. In most cases this will only require removing the parenthesis.

setter and getter methods that have additional optional arguments will need to have those arguments implemented in another way, either as a separate property in the same class or as attributes or properties of another class.

Cases where the setter returns a value will need to be changed to using the setter followed by the getter.

Cases where there are set_ATTR_on() and set_ATTR_off() methods will be changed to ATTR_on properties.

84.7.7 Examples

axes.Axes.set_axis_off/set_axis_on

Current implementation:

```python
axes.Axes.set_axis_off()
axes.Axes.set_axis_on()
```

New implementation:

```python
True = axes.Axes.axis_on
False = axes.Axes.axis_on
axes.Axes.axis_on = True
axes.Axes.axis_on = False
```
**axes.Axes.get_xlim/set_xlim and get_autoscalex_on/set_autoscalex_on**

Current implementation:

```python
left, right = axes.Axes.get_xlim()
auto = axes.Axes.get_autoscalex_on()

left, right = axes.Axes.set_xlim(left=left, right=right, emit=emit, auto=auto)
left, right = axes.Axes.set_xlim(left=left, right=None, emit=emit, auto=auto)
left, right = axes.Axes.set_xlim(left=None, right=right, emit=emit, auto=auto)
left, right = axes.Axes.set_xlim(left=left, emit=emit, auto=auto)
left, right = axes.Axes.set_xlim(right=right, emit=emit, auto=auto)

axes.Axes.set_autoscalex_on(auto)
```

New implementation:

```python
left, right = axes.Axes.axes_xlim
auto = axes.Axes.autoscalex_on

axes.Axes.axes_xlim = [left, right]
axes.Axes.axes_xlim = [left, None]
axes.Axes.axes_xlim = [None, right]
axes.Axes.axes_xlim[0] = left
axes.Axes.axes_xlim[1] = right

axes.Axes.autoscalex_on = auto
axes.Axes.emit_xlim = emit
```

**axes.Axes.get_title/set_title**

Current implementation:

```python
string = axes.Axes.get_title()
axes.Axes.set_title(string, fontdict=fontdict, **kwargs)
```

New implementation:

```python
string = axes.Axes.title
string = axes.Axes.title_text.text

text.Text = axes.Axes.title_text
text.Text.<attribute> = attribute
text.Text.fontdict = fontdict

axes.Axes.title = string
axes.Axes.title = text.Text
axes.Axes.title_text = string
axes.Axes.title_text = text.Text
```
axes.Axes.get_xticklabels/set_xticklabels

Current implementation:

```
[text.Text] = axes.Axes.get_xticklabels()
[text.Text] = axes.Axes.get_xticklabels(minor=False)
[text.Text] = axes.Axes.get_xticklabels(minor=True)
[text.Text] = axes.Axes.([string], fontdict=None, **kwargs)
[text.Text] = axes.Axes.([string], fontdict=None, minor=False, **kwargs)
[text.Text] = axes.Axes.([string], fontdict=None, minor=True, **kwargs)
```

New implementation:

```
[text.Text] = axes.Axes.xticklabels
[text.Text] = axes.Axes.xminorticklabels
axes.Axes.xticklabels = [string]
axes.Axes.xminorticklabels = [string]
axes.Axes.xticklabels = [text.Text]
axes.Axes.xminorticklabels = [text.Text]
```

84.7.8 Alternatives

Instead of using decorators, it is also possible to use the property function. This would change the procedure so that all getter methods that lack a prefix will need to be renamed or removed. This makes handling docstrings more difficult and harder to read.

It is not necessary to deprecate the setter and getter methods, but leaving them in will complicate the code.

This could also serve as an opportunity to rewrite or even remove automatic alias generation.

Another alternate proposal:

Convert set_xlim, set_xlabel, set_title, etc. to xlim, xlabel, title,... to make the transition from plt functions to axes methods significantly simpler. These would still be methods, not properties, but it’s still a great usability enhancement while retaining the interface.

84.8 MEP14: Text handling

- Status
- Branches and Pull requests
- Abstract
- Detailed description
- Implementation
- Backward compatibility
84.8.1 Status

- Discussion

84.8.2 Branches and Pull requests

Issue #253 demonstrates a bug where using the bounding box rather than the advance width of text results in misaligned text. This is a minor point in the grand scheme of things, but it should be addressed as part of this MEP.

84.8.3 Abstract

By reorganizing how text is handled, this MEP aims to:
- improve support for Unicode and non-ltr languages
- improve text layout (especially multi-line text)
- allow support for more fonts, especially non-Apple-format TrueType fonts and OpenType fonts.
- make the font configuration easier and more transparent

84.8.4 Detailed description

Text layout

At present, matplotlib has two different ways to render text: “built-in” (based on FreeType and our own Python code), and “usetex” (based on calling out to a TeX installation). Adjunct to the “built-in” renderer there is also the Python-based “mathtext” system for rendering mathematical equations using a subset of the TeX language without having a TeX installation available. Support for these two engines in strewn about many source files, including every backend, where one finds clauses like

```
if rcParams['text.usetex']:
    # do one thing else:
    # do another
```

Adding a third text rendering approach (more on that later) would require editing all of these places as well, and therefore doesn’t scale.

Instead, this MEP proposes adding a concept of “text engines”, where the user could select one of many different approaches for rendering text. The implementations of each of these would be localized to their own set of modules, and not have little pieces around the whole source tree.

Why add more text rendering engines? The “built-in” text rendering has a number of shortcomings.
- It only handles right-to-left languages, and doesn’t handle many special features of Unicode, such as combining diacriticals.
The multiline support is imperfect and only supports manual line-breaking – it can not break up a paragraph into lines of a certain length.

It also does not handle inline formatting changes in order to support something like Markdown, reStructuredText or HTML. (Though rich-text formatting is contemplated in this MEP, since we want to make sure this design allows it, the specifics of a rich-text formatting implementation is outside of the scope of this MEP.)

Supporting these things is difficult, and is the “full-time job” of a number of other projects:

- pango/harfbuzz
- QtTextLayout
- Microsoft DirectWrite
- Apple Core Text

Of the above options, it should be noted that harfbuzz is designed from the start as a cross platform option with minimal dependencies, so therefore is a good candidate for a single option to support.

Additionally, for supporting rich text, we could consider using WebKit, and possibly whether than represents a good single cross-platform option. Again, however, rich text formatting is outside of the scope of this project.

Rather than trying to reinvent the wheel and add these features to matplotlib’s “built-in” text renderer, we should provide a way to leverage these projects to get more powerful text layout. The “built-in” renderer will still need to exist for reasons of ease of installation, but its feature set will be more limited compared to the others. [TODO: This MEP should clearly decide what those limited features are, and fix any bugs to bring the implementation into a state of working correctly in all cases that we want it to work. I know @leejjoon has some thoughts on this.]

Font selection

Going from an abstract description of a font to a file on disk is the task of the font selection algorithm – it turns out to be much more complicated than it seems at first.

The “built-in” and “usetex” renderers have very different ways of handling font selection, given their different technologies. TeX requires the installation of TeX-specific font packages, for example, and can not use TrueType fonts directly. Unfortunately, despite the different semantics for font selection, the same set of font properties are used for each. This is true of both the FontProperties class and the font-related rcParams (which basically share the same code underneath). Instead, we should define a core set of font selection parameters that will work across all text engines, and have engine-specific configuration to allow the user to do engine-specific things when required. For example, it is possible to directly select a font by name in the “built-in” using font.family, but the same is not possible with “usetex”. It may be possible to make it easier to use TrueType fonts by using XeTeX, but users will still want to use the traditional metafonts through TeX font packages. So the issue still stands that different text engines will need engine-specific configuration, and it should be more obvious to the user which configuration will work across text engines and which are engine-specific.

Note that even excluding “usetex”, there are different ways to find fonts. The default is to use the font list cache in font_manager.py which matches fonts using our own algorithm based on the CSS font matching algorithm. It doesn’t always do the same thing as the native font selection algorithms on Linux (fontconfig), Mac and Windows, and it doesn’t always find all of the fonts on the system that the OS would normally
pick up. However, it is cross-platform, and always finds the fonts that ship with matplotlib. The Cairo and MacOSX backends (and presumably a future HTML5-based backend) currently bypass this mechanism and use the OS-native ones. The same is true when not embedding fonts in SVG, PS or PDF files and opening them in a third-party viewer. A downside there is that (at least with Cairo, need to confirm with MacOSX) they don’t always find the fonts we ship with matplotlib. (It may be possible to add the fonts to their search path, though, or we may need to find a way to install our fonts to a location the OS expects to find them).

There are also special modes in the PS and PDF to only use the core fonts that are always available to those formats. There, the font lookup mechanism must only match against those fonts. It is unclear whether the OS-native font lookup systems can handle this case.

There is also experimental support for using fontconfig for font selection in matplotlib, turned off by default. Fontconfig is the native font selection algorithm on Linux, but is also cross platform and works well on the other platforms (though obviously is an additional dependency there).

Many of the text layout libraries proposed above (pango, QtTextLayout, DirectWrite and CoreText etc.) insist on using the font selection library from their own ecosystem.

All of the above seems to suggest that we should move away from our self-written font selection algorithm and use the native APIs where possible. That’s what Cairo and MacOSX backends already want to use, and it will be a requirement of any complex text layout library. On Linux, we already have the bones of a fontconfig implementation (which could also be accessed through pango). On Windows and Mac we may need to write custom wrappers. The nice thing is that the API for font lookup is relatively small, and essentially consist of “given a dictionary of font properties, give me a matching font file”.

**Font subsetting**

Font subsetting is currently handled using ttconv. Ttconv was a standalone commandline utility for converting TrueType fonts to subsetted Type 3 fonts (among other features) written in 1995, which matplotlib (well, I) forked in order to make it work as a library. It only handles Apple-style TrueType fonts, not ones with the Microsoft (or other vendor) encodings. It doesn’t handle OpenType fonts at all. This means that even though the STIX fonts come as .otf files, we have to convert them to .ttf files to ship them with matplotlib. The Linux packagers hate this — they’d rather just depend on the upstream STIX fonts. Ttconv has also been shown to have a few bugs that have been difficult to fix over time.

Instead, we should be able to use FreeType to get the font outlines and write our own code (probably in Python) to output subsetted fonts (Type 3 on PS and PDF and SVGFonts or paths on SVG). FreeType, as a popular and well-maintained project, handles a wide variety of fonts in the wild. This would remove a lot of custom C code, and remove some code duplication between backends.

Note that subsetting fonts this way, while the easiest route, does lose the hinting in the font, so we will need to continue, as we do now, provide a way to embed the entire font in the file where possible.

Alternative font subsetting options include using the subsetting built-in to Cairo (not clear if it can be used without the rest of Cairo), or using fontforge (which is a heavy and not terribly cross-platform dependency).

**Freetype wrappers**

Our FreeType wrapper could really use a reworking. It defines its own image buffer class (when a Numpy array would be easier). While FreeType can handle a huge diversity of font files, there are limitations to our wrapper that make it much harder to support non-Apple-vendor TrueType files, and certain features of
OpenType files. (See #2088 for a terrible result of this, just to support the fonts that ship with Windows 7 and 8). I think a fresh rewrite of this wrapper would go a long way.

**Text anchoring and alignment and rotation**

The handling of baselines was changed in 1.3.0 such that the backends are now given the location of the baseline of the text, not the bottom of the text. This is probably the correct behavior, and the MEP refactoring should also follow this convention.

In order to support alignment on multi-line text, it should be the responsibility of the (proposed) text engine to handle text alignment. For a given chunk of text, each engine calculates a bounding box for that text and the offset of the anchor point within that box. Therefore, if the va of a block was “top”, the anchor point would be at the top of the box.

Rotating of text should always be around the anchor point. I’m not sure that lines up with current behavior in matplotlib, but it seems like the sanest/least surprising choice. [This could be revisited once we have something working]. Rotation of text should not be handled by the text engine – that should be handled by a layer between the text engine and the rendering backend so it can be handled in a uniform way. [I don’t see any advantage to rotation being handled by the text engines individually...]

There are other problems with text alignment and anchoring that should be resolved as part of this work. [TODO: enumerate these].

**Other minor problems to fix**

The mathtext code has backend-specific code – it should instead provide its output as just another text engine. However, it’s still desirable to have mathtext layout inserted as part of a larger layout performed by another text engine, so it should be possible to do this. It’s an open question whether embedding the text layout of an arbitrary text engine in another should be possible.

The text mode is currently set by a global rcParam (“text.usetex”) so it’s either all on or all off. We should continue to have a global rcParam to choose the text engine (“text.layout_engine”), but it should under the hood be an overridable property on the Text object, so the same figure can combine the results of multiple text layout engines if necessary.

**84.8.5 Implementation**

A concept of a “text engine” will be introduced. Each text engine will implement a number of abstract classes. The TextFont interface will represent text for a given set of font properties. It isn’t necessarily limited to a single font file – if the layout engine supports rich text, it may handle a number of font files in a family. Given a TextFont instance, the user can get a TextLayout instance, which represents the layout for a given string of text in a given font. From a TextLayout, an iterator over TextSpans is returned so the engine can output raw editable text using as few spans as possible. If the engine would rather get individual characters, they can be obtained from the TextSpan instance:

```python
class TextFont(TextFontBase):
    def __init__(self, font_properties):
        """
        Create a new object for rendering text using the given font properties.
        """
        pass
```
```python
def get_layout(self, s, ha, va):
    """
    Get the TextLayout for the given string in the given font and
    the horizontal (left, center, right) and verticalalignment (top,
    center, baseline, bottom)
    """
    pass

class TextLayout(TextLayoutBase):
    def get_metrics(self):
        """
        Return the bounding box of the layout, anchored at (0, 0).
        """
        pass

    def get_spans(self):
        """
        Returns an iterator over the spans of different in the layout.
        This is useful for backends that want to editable raw text as
        individual lines. For rich text where the font may change,
        each span of different font type will have its own span.
        """
        pass

    def get_image(self):
        """
        Returns a rasterized image of the text. Useful for raster backends,
        like Agg.

        In all likelihood, this will be overridden in the backend, as it can
        be created from get_layout(), but certain backends may want to
        override it if their library provides it (as freetype does).
        """
        pass

    def get_rectangles(self):
        """
        Returns an iterator over the filled black rectangles in the layout.
        Used by TeX and mathtext for drawing, for example, fraction lines.
        """
        pass

    def get_path(self):
        """
        Returns a single Path object of the entire layed out text.

        [Not strictly necessary, but might be useful for textpath
        functionality]
        """
        pass

class TextSpan(TextSpanBase):
    x, y  # Position of the span -- relative to the text layout as a whole
```
Graphic backends that want to output subset of fonts would likely build up a file-global dictionary of characters where the keys are (fontname, glyph_id) and the values are the paths so that only one copy of the path for each character will be stored in the file.

Special casing: The “usetex” functionality currently is able to get Postscript directly from TeX to insert directly in a Postscript file, but for other backends, parses a DVI file and generates something more abstract. For a case like this, TextLayout would implement get_spans for most backends, but add get_ps for the Postscript backend, which would look for the presence of this method and use it if available, or fall back to get_spans. This kind of special casing may also be necessary, for example, when the graphics backend and text engine belong to the same ecosystem, e.g. Cairo and Pango, or MacOSX and CoreText.

There are three main pieces to the implementation:

1. Rewriting the freetype wrapper, and removing ttconv.
2. Once (1) is done, as a proof of concept, we can move to the upstream STIX .otf fonts
3. Add support for web fonts loaded from a remote URL. (Enabled by using freetype for font subsetting).
4. Refactoring the existing “builtin” and “usetex” code into separate text engines and to follow the API outlined above.
5. Implementing support for advanced text layout libraries.
(1) and (2) are fairly independent, though having (1) done first will allow (2) to be simpler. (3) is dependent on (1) and (2), but even if it doesn’t get done (or is postponed), completing (1) and (2) will make it easier to move forward with improving the “builtin” text engine.

### 84.8.6 Backward compatibility

The layout of text with respect to its anchor and rotation will change in hopefully small, but improved, ways. The layout of multiline text will be much better, as it will respect horizontal alignment. The layout of bidirectional text or other advanced Unicode features will now work inherently, which may break some things if users are currently using their own workarounds.

Fonts will be selected differently. Hacks that used to sort of work between the “builtin” and “usetex” text rendering engines may no longer work. Fonts found by the OS that weren’t previously found by matplotlib may be selected.

### 84.8.7 Alternatives

TBD

### 84.9 MEP15 - Fix axis autoscaling when limits are specified for one axis only

- **Status**
- **Branches and Pull requests**
- **Abstract**
- **Detailed description**
- **Implementation**
- **Backward compatibility**
- **Alternatives**

#### 84.9.1 Status

Discussion

#### 84.9.2 Branches and Pull requests

None so far.
84.9.3 Abstract

When one axis of a 2-dimensional plot is overridden via xlim or ylim, automatic scaling of the remaining axis should be based on the data that falls within the specified limits of the first axis.

84.9.4 Detailed description

When axis limits for a 2-D plot are specified for one axis only (via xlim or ylim), matplotlib currently does not currently rescale the other axis. The result is that the displayed curves or symbols may be compressed into a tiny portion of the available area, so that the final plot conveys much less information than it would with appropriate axis scaling.

The proposed change of behavior would make matplotlib choose the scale for the remaining axis using only the data that falls within the limits for the axis where limits were specified.

84.9.5 Implementation

I don’t know enough about the internals of matplotlib to be able to suggest an implementation.

84.9.6 Backward compatibility

From the standpoint of software interfaces, there would be no break in backward compatibility. Some outputs would be different, but if the user truly desires the previous behavior, he/she can achieve this by overriding the axis scaling for both axes.

84.9.7 Alternatives

The only alternative that I can see is to maintain the status quo.

84.10 MEP19: Continuous Integration

84.10.1 Status

Discussion

84.10.2 Branches and Pull requests

84.10.3 Abstract

matplotlib could benefit from better and more reliable continuous integration, both for testing and building installers and documentation.
84.10.4 Detailed description

Current state-of-the-art

Testing

matplotlib currently uses Travis-CI for automated tests. While Travis-CI should be praised for how much it does as a free service, it has a number of shortcomings:

- It often fails due to network timeouts when installing dependencies.
- It often fails for inexplicable reasons.
- Build or test products can only be saved from build off of branches on the main repo, not pull requests, so it is often difficult to “post mortem” analyse what went wrong. This is particularly frustrating when the failure can not be subsequently reproduced locally.
- It is not extremely fast. matplotlib’s cpu and memory requirements for testing are much higher than the average Python project.
- It only tests on Ubuntu Linux, and we have only minimal control over the specifics of the platform. It can be upgraded at any time outside of our control, causing unexpected delays at times that may not be convenient in our release schedule.

On the plus side, Travis-CI’s integration with github – automatically testing all pending pull requests – is exceptional.

Builds

There is no centralized effort for automated binary builds for matplotlib. However, the following disparate things are being done [If the authors mentioned here could fill in detail, that would be great!]:

- @sandrotosi: builds Debian packages
- @takluyver: Has automated Ubuntu builds on Launchpad
- @cgholkke: Makes Windows builds (don’t know how automated that is)
- @r-owen: Makes OS-X builds (don’t know how automated that is)

Documentation

Documentation of master is now built by travis and uploaded to http://matplotlib.org/devdocs/index.html

@NelleV, I believe, generates the docs automatically and posts them on the web to chart MEP10 progress.

Peculiarities of matplotlib

matplotlib has complex requirements that make testing and building more taxing than many other Python projects.

- The CPU time to run the tests is quite high. It puts us beyond the free accounts of many CI services (e.g. ShiningPanda)
- It has a large number of dependencies, and testing the full matrix of all combinations is impractical. We need to be clever about what space we test and guarantee to support.
Requirements

This section outlines the requirements that we would like to have.

1. Testing all pull requests by hooking into the Github API, as Travis-CI does

2. Testing on all major platforms: Linux, Mac OS-X, MS Windows (in that order of priority, based on user survey)

3. Retain the last n days worth of build and test products, to aid in post-mortem debugging.

4. Automated nightly binary builds, so that users can test the bleeding edge without installing a complete compilation environment.

5. Automated benchmarking. It would be nice to have a standard benchmark suite (separate from the tests) whose performance could be tracked over time, in different backends and platforms. While this is separate from building and testing, ideally it would run on the same infrastructure.

6. Automated nightly building and publishing of documentation (or as part of testing, to ensure PRs don’t introduce documentation bugs). (This would not replace the static documentation for stable releases as a default).

7. The test systems should be manageable by multiple developers, so that no single person becomes a bottleneck. (Travis-CI’s design does this well – storing build configuration in the git repository, rather than elsewhere, is a very good design.)

8. Make it easy to test a large but sparse matrix of different versions of matplotlib’s dependencies. The matplotlib user survey provides some good data as to where to focus our efforts: https://docs.google.com/spreadsheet/ccc?key=0AjPjTMRTwTdhpQS25pcTzIRWdqX0pNckNSU01sMHc#gid=0

9. Nice to have: A decentralized design so that those with more obscure platforms can publish build results to a central dashboard.

84.10.5 Implementation

This part is yet-to-be-written.

However, ideally, the implementation would be a third-party service, to avoid adding system administration to our already stretched time. As we have some donated funds, this service may be a paid one if it offers significant time-saving advantages over free offerings.

84.10.6 Backward compatibility

Backward compatibility is not a major concern for this MEP. We will replace current tools and procedures with something better and throw out the old.

84.10.7 Alternatives

84.10.8 Hangout Notes
CI Infrastructure

- We like Travis and it will probably remain part of our arsenal in any event. The reliability issues are being looked into.
- Enable Amazon S3 uploads of testing products on Travis. This will help with post-mortem of failures (@mdboom is looking into this now).
- We want Mac coverage. The best bet is probably to push Travis to enable it for our project by paying them for a Pro account (since they don’t otherwise allow testing on both Linux and Mac).
- We want Windows coverage. Shining Panda is an option there.
- Investigate finding or building a tool that would collect and synthesize test results from a number of sources and post it to Github using the Github API. This may be of general use to the Scipy community.
- For both Windows and Mac, we should document (or better yet, script) the process of setting up the machine for a build, and how to build binaries and installers. This may require getting information from Russel Owen and Christoph Gohlke. This is a necessary step for doing automated builds, but would also be valuable for a number of other reasons.

The test framework itself

- We should investigate ways to make it take less time
  - Eliminating redundant tests, if possible
  - General performance improvements to matplotlib will help
- We should be covering more things, particularly more backends
- We should have more unit tests, fewer integration tests, if possible

84.11 MEP21: color and cm refactor

- **Status**
- **Branches and Pull requests**
- **Abstract**
- **Detailed description**
- **Implementation**
- **Backward compatibility**
- **Alternatives**
84.11.1 Status

- **Discussion**: This MEP has not commenced yet, but here are some ongoing ideas which may become a part of this MEP:

84.11.2 Branches and Pull requests

84.11.3 Abstract

- **color**
  - tidy up the namespace
  - Define a “Color” class
  - make it easy to convert from one color type to another `hex -> RGB`, `RGB -> hex`, `HSV -> RGB` etc.
  - improve the construction of a colormap - the dictionary approach is archaic and overly complex (though incredibly powerful)
  - make it possible to interpolate between two or more color types in different modes, especially useful for construction of colormaps in HSV space for instance

- **cm**
  - rename the module to something more descriptive - mappables?

Overall, there are a lot of improvements that can be made with matplotlib color handling - managing backwards compatibility will be difficult as there are some badly named variables/modules which really shouldn’t exist - but a clear path and message for migration should be available, with a large amount of focus on this in the API changes documentation.

84.11.4 Detailed description

- Navigation by events: https://github.com/matplotlib/matplotlib/pull/3652

84.12.3 Abstract

The main goal of this MEP is to make it easier to modify (add, change, remove) the way the user interacts with the figures.

The user interaction with the figure is deeply integrated within the Canvas and Toolbar. Making extremely difficult to do any modification.

This MEP proposes the separation of this interaction into Toolbar, Navigation and Tools to provide independent access and reconfiguration.

This approach will make easier to create and share tools among users. In the far future, we can even foresee a kind of Marketplace for Tools where the most popular can be added into the main distribution.
84.12.4 Detailed description

The reconfiguration of the Toolbar is complex, most of the time it requires a custom backend.

The creation of custom Tools sometimes interferes with the Toolbar, as example see https://github.com/matplotlib/matplotlib/issues/2694 also the shortcuts are hardcoded and again not easily modifiable https://github.com/matplotlib/matplotlib/issues/2699

The proposed solution is to take the actions out of the Toolbar and the shortcuts out of the Canvas. This actions and shortcuts will be in the form of Tools.

A new class Navigation will be the bridge between the events from the Canvas and Toolbar and redirect them to the appropriate Tool.

At the end the user interaction will be divided into three classes:

- NavigationBase: This class is instantiated for each FigureManager and connect the all user interactions with the Tools
- ToolbarBase: This existing class is relegated only as a GUI access to Tools.
- ToolBase: Is the basic definition of Tools.

84.12.5 Implementation

ToolBase(object)

Tools can have a graphical representation as the SubplotTool or not even be present in the Toolbar as Quit

The ToolBase has the following class attributes for configuration at definition time

- keymap = None: Key(s) to be used to trigger the tool
- description = ‘’: Small description of the tool
- image = None: Image that is used in the toolbar

The following instance attributes are set at instantiation:

- name
- navigation

Methods

- trigger(self, event): This is the main method of the Tool, it is called when the Tool is triggered by: * Toolbar button click * keypress associated with the Tool Keypmap * Call to navigation.trigger_tool(name)
- set_figure(self, figure): Set the figure and navigation attributes
- destroy(self, *args): Destroy the Tool graphical interface (if exists)

Available Tools

- ToolQuit
• ToolEnableAllNavigation
• ToolEnableNavigation
• ToolToggleGrid
• ToolToggleFullScreen
• ToolToggleYScale
• ToolToggleXScale
• ToolHome
• ToolBack
• ToolForward
• SaveFigureBase
• ConfigureSubplotsBase

**ToolToggleBase(ToolBase)**

The ToolToggleBase has the following class attributes for configuration at definition time

- radio_group = None: Attribute to group ‘radio’ like tools (mutually exclusive)
- cursor = None: Cursor to use when the tool is active

The Toggleable Tools, can capture keypress, mouse moves, and mouse button press

**It defines the following methods**

- enable(self, event): Called by ToolToggleBase.trigger method
- disable(self, event): Called when the tool is untoggled
- toggled : Property True or False

**Available Tools**

- ToolZoom
- ToolPan

**NavigationBase**

**Defines the following attributes**

- canvas:
- keypresslock: **Lock to know if the canvas key_press_event** is available and process it
- messagelock: Lock to know if the message is available to write

**Public methods for User use:**

- nav_connect(self, s, func): Connect to navigation for events
• nav_disconnect(self, cid): Disconnect from navigation event
• message_event(self, message, sender=None): Emit a tool_message_event event
• active_toggle(self): Property The currently toggled tools or None
• get_tool_keymap(self, name): Return a list of keys that are associated with the tool
• set_tool_keymap(self, name, *keys): Set the keys for the given tool
• remove_tool(self, name): Removes tool from the navigation control.
• add_tools(self, tools): Add multiple tools to Navigation
• add_tool(self, name, tool, group=None, position=None): Add a tool to the Navigation
• tool_trigger_event(self, name, sender=None, canvasevent=None, data=None): Trigger a tool and fire the event
• tools(self) Property: Return a dict with available tools with corresponding keymaps, descriptions and objects
• get_tool(self, name): Return the tool object

**ToolbarBase**

**Methods for Backend implementation**

• add_toolitem(self, name, group, position, image, description, toggle): Add a toolitem to the toolbar. This method is a callback from tool_added_event (emited by navigation)
• set_message(self, s): Display a message on toolbar or in status bar
• toggle_toolitem(self, name): Toggle the toolitem without firing event.
• remove_toolitem(self, name): Remove a toolitem from the Toolbar

84.12.6 Backward compatibility

For backward compatibility added a ‘navigation’ key to rcsetup.validate_toolbar, that is used for Navigation classes instantiation instead of the NavigationToolbar2 classes

With this parameter, it makes it transparent to anyone using the existing backends.

[@pelson comment: This also gives us an opportunity to avoid needing to implement all of this in the same PR - some backends can potentially exist without the new functionality for a short while (but it must be done at some point).]

84.13 MEP23: Multiple Figures per GUI window
84.13.1 Status

Discussion

84.13.2 Branches and Pull requests

Previous work - https://github.com/matplotlib/matplotlib/pull/2465 To-delete

84.13.3 Abstract

Add the possibility to have multiple figures grouped under the same FigureManager

84.13.4 Detailed description

Under the current structure, every canvas has its own window.

This is and may continue to be the desired method of operation for most use cases.

Sometimes when there are too many figures open at the same time, it is desirable to be able to group these under the same window [see](https://github.com/matplotlib/matplotlib/issues/2194).

The proposed solution modifies FigureManagerBase to contain and manage more than one canvas. The settings parameter rcParams['backend.multifigure'] control when the MultiFigure behaviour is desired.

Note
It is important to note, that the proposed solution, assumes that the [MEP22](https://github.com/matplotlib/matplotlib/wiki/Mep22) is already in place. This is simply because the actual implementation of the Toolbar makes it pretty hard to switch between canvases.

### 84.13.5 Implementation

The first implementation will be done in GTK3 using a Notebook as canvas container.

**FigureManagerBase**

will add the following new methods

- **add_canvas**: To add a canvas to an existing FigureManager object
- **remove_canvas**: To remove a canvas from a FigureManager object, if it is the last one, it will be destroyed
- **move_canvas**: To move a canvas from one FigureManager to another.
- **set_canvas_title**: To change the title associated with a specific canvas container
- **get_canvas_title**: To get the title associated with a specific canvas container
- **get_active_canvas**: To get the canvas that is in the foreground and is subject to the gui events. There is no set_active_canvas because the active canvas, is defined when show is called on a Canvas object.

**new_figure_manager**

To control which FigureManager will contain the new figures, an extra optional parameter figuremanager will be added, this parameter value will be passed to new_figure_manager_given_figure

**new_figure_manager_given_figure**

- If figuremanager parameter is give, this FigureManager object will be used instead of creating a new one.
- If rcParams['backend.multifigure'] == True: The last FigureManager object will be used instead of creating a new one.

**NavigationBase**

Modifies the NavigationBase to keep a list of canvases, directing the actions to the active one.
84.13.6 Backward compatibility

For the MultiFigure properties to be visible, the user has to activate them directly setting
rcParams['backend.multifigure'] = True

It should be backwards compatible for backends that adhere to the current FigureManagerBase structure
even if they have not implemented the MultiFigure magic yet.

84.13.7 Alternatives

Instead of modifying the FigureManagerBase it could be possible to add a parallel class, that handles the
cases where rcParams['backend.multifigure'] = True. This will warranty that there won’t be any
problems with custom made backends, but also makes bigger the code, and more things to maintain.

84.14 MEP24: negative radius in polar plots

None

84.14.3 Abstract

It is clear that polar plots need to be able to gracefully handle negative r values (not by clipping or reflection).
84.14.4 Detailed description

One obvious application that we should support is bB plots (see https://github.com/matplotlib/matplotlib/issues/1730#issuecomment-40815837), but this seems more generally useful (for example growth rate as a function of angle). The assumption in the current code (as I understand it) is that the center of the graph is \( r=0 \), however it would be good to be able to set the center to be at any \( r \) (with any value less than the offset clipped).

- related pull requests:
84.15.3 Abstract

This MEP aims at adding a serializable Controller objects to act as an Artist managers. Users would then communicate changes to an Artist via a Controller. In this way, functionality of the Controller objects may be added incrementally since each Artist is still responsible for drawing everything. The goal is to create an API that is usable both by graphing libraries requiring high-level descriptions of figures and libraries requiring low-level interpretations.

84.15.4 Detailed description

Matplotlib is a core plotting engine with an API that many users already understand. It’s difficult/impossible for other graphing libraries to (1) get a complete figure description, (2) output raw data from the figure object as the user has provided it, (3) understand the semantics of the figure objects without heuristics, and (4) give matplotlib a complete figure description to visualize. In addition, because an Artist has no conception of its own semantics within the figure, it’s difficult to interact with them in a natural way.

In this sense, matplotlib will adopt a standard Model-View-Controller (MVC) framework. The Model will be the user defined data, style, and semantics. The Views are the ensemble of each individual Artist, which are responsible for producing the final image based on the model. The Controller will be the Controller object managing its set of Artist objects.

The Controller must be able to export the information that it’s carrying about the figure on command, perhaps via a to_json method or similar. Because it would be extremely extraneous to duplicate all of the information in the model with the controller, only user-specified information (data + style) are explicitly kept. If a user wants more information (defaults) from the view/model, it should be able to query for it.

• This might be annoying to do, non-specified kwargs are pulled from the rcParams object which is in turn created from reading a user specified file and can be dynamically changed at run time. I suppose we could keep a dict of default defaults and compare against that. Not clear how this will interact with the style sheet [[MEP26]] - @tacaswell

Additional Notes:

• The raw data does not necessarily need to be a list, ndarray, etc. Rather, it can more abstractly just have a method to yield data when needed.

• Because the Controller will contain extra information that users may not want to keep around, it should not be created by default. You should be able to both (a) instantiate a Controller with a figure and (b) build a figure with a Controller.

Use Cases:

• Export all necessary informat

• Serializing a matplotlib figure, saving it, and being able to rerun later.

• Any other source sending an appropriately formatted representation to matplotlib to open

84.15.5 Examples

Here are some examples of what the controllers should be able to do.
1. Instantiate a matplotlib figure from a serialized representation (e.g., JSON):

```python
import json
from matplotlib.controllers import Controller
with open('my_figure') as f:
    o = json.load(f)
    c = Controller(o)
    fig = c.figure
```

2. Manage artists from the controller (e.g., Line2D):

```python
# not really sure how this should look
    c.axes[0].lines[0].color = 'b'
# ?
```

3. Export serializable figure representation:

```python
    o = c.to_json()
    # or... we should be able to throw a figure object in there too
    o = Controller.to_json(mpl_fig)
```

### 84.15.6 Implementation

1. Create base `Controller` objects that are able to manage `Artist` objects (e.g., Hist)

   Comments:
   - initialization should happen via unpacking **`, so we need a copy of call signature parameter for the Artist we’re ultimately trying to control. Unfortunate hard-coded repetition...`
   - should the additional `**kwargs` accepted by each `Artist` be tracked at the `Controller`
   - how does a `Controller` know which artist belongs where? E.g., do we need to pass `axes` references?

   Progress:
   - A simple NB demonstrating some functionality for `Line2DController` objects: https://nbviewer.jupyter.org/gist/theengineear/f0aa8d79f64325e767c0

2. Write in protocols for the `Controller` to update the model.

   Comments:
   - how should containers be dealt with? E.g., what happens to old patches when we re-bin a histogram?
   - in the link from (1), the old line is completely destroyed and redrawn, what if something is referencing it?

3. Create method by which a json object can be assembled from the `Controllers`

4. Deal with serializing the unserializable aspects of a figure (e.g., non-affine transforms?)
5. Be able to instantiate from a serialized representation
6. Reimplement the existing pyplot and Axes method, e.g. `pyplot.hist` and `Axes.hist` in terms of the new controller class.

> @theengineer: in #2 above, what do you mean by `get updates` from each `Artist`?

^ Yup. The Controller shouldn’t need to get updated. This just happens in #3. Delete comments when you see this.

### 84.15.7 Backward compatibility

- pickling will change
- non-affine transformations will require a defined pickling method

### 84.15.8 Alternatives

PR #3150 suggested adding semantics by parasitically attaching extra containers to axes objects. This is a more complete solution with what should be a more developed/flexible/powerful framework.

84.16.1 Status

Proposed

84.16.2 Branches and Pull requests

84.16.3 Abstract

This MEP proposes a new stylesheet implementation to allow more comprehensive and dynamic styling of artists.

The current version of matplotlib (1.4.0) allows stylesheets based on the rcParams syntax to be applied before creation of a plot. The methodology below proposes a new syntax, based on CSS, which would allow styling of individual artists and properties, which can be applied dynamically to existing objects.

This is related to (and makes steps toward) the overall goal of moving to a DOM/tree-like architecture.

84.16.4 Detailed description

Currently, the look and appearance of existing artist objects (figure, axes, Line2D etc...) can only be updated via set_ and get_ methods on the artist object, which is quite laborious, especially if no reference to the artist(s) has been stored. The new style sheets introduced in 1.4 allow styling before a plot is created, but do not offer any means to dynamically update plots or distinguish between artists of the same type (i.e. to specify the line color and line style separately for differing Line2D objects).

The initial development should concentrate on allowing styling of artist primitives (those artists that do not contain other artists), and further development could expand the CSS syntax rules and parser to allow more complex styling. See the appendix for a list of primitives.

The new methodology would require development of a number of steps:

- A new stylesheet syntax (likely based on CSS) to allow selection of artists by type, class, id etc...
- A mechanism by which to parse a stylesheet into a tree
- A mechanism by which to translate the parse-tree into something which can be used to update the properties of relevant artists. Ideally this would implement a method by which to traverse the artists in a tree-like structure.
- A mechanism by which to generate a stylesheet from existing artist properties. This would be useful to allow a user to export a stylesheet from an existing figure (where the appearance may have been set using the matplotlib API)...
84.16.5 Implementation

It will be easiest to allow a ‘3rd party’ to modify/set the style of an artist if the ‘style’ is created as a separate class and store against the artist as a property. The GraphicsContext class already provides a basis for a Style class and an artists draw method can be refactored to use the Style class rather than setting up its own GraphicsContext and transferring it’s style-related properties to it. A minimal example of how this could be implemented is shown here: https://github.com/JamesRamm/mpl_experiment

IMO, this will also make the API and code base much neater as individual get/set methods for artist style properties are now redundant... Indirectly related would be a general drive to replace get/set methods with properties. Implementing the style class with properties would be a big stride toward this...

For initial development, I suggest developing a syntax based on a much (much much) simplified version of CSS. I am in favour of dubbing this Artist Style Sheets :

BNF Grammar

I propose a very simple syntax to implement initially (like a proof of concept), which can be expanded upon in the future. The BNF form of the syntax is given below and then explained

```
RuleSet ::= SelectorSequence "{"Declaration"}"
SelectorSequence ::= Selector {"," Selector}
Declaration ::= propName":" propValue";"
Selector ::= ArtistIdent"#"Ident
propName ::= Ident
propValue ::= Ident | Number | Colour | "None"
```

ArtistIdent, Ident, Number and Colour are tokens (the basic building blocks of the expression) which are defined by regular expressions.

Syntax

A CSS stylesheet consists of a series of rule sets in hierarchical order (rules are applied from top to bottom). Each rule follows the syntax

```
selector {attribute: value;}
```

Each rule can have any number of attribute: value pairs, and a stylesheet can have any number of rules.

The initial syntax is designed only for artist primitives. It does not address the question of how to set properties on container types (whose properties may themselves be artists with settable properties), however, a future solution to this could simply be nested RuleSet s
Selectors

Selectors define the object to which the attribute updates should be applied. As a starting point, I propose just 2 selectors to use in initial development:

**Artist Type Selector**

Select an artist by its type. E.g Line2D or Text:

```plaintext
Line2D {attribute: value}
```

The regex for matching the artist type selector (ArtistIdent in the BNF grammar) would be:

```plaintext
ArtistIdent = r'(?P<ArtistIdent>Line2D|bText|bAxesImage|bFigureImage|bPatch)'
```

**GID selector**

Select an artist by its gid:

```plaintext
Line2D#myGID {attribute: value}
```

A gid can be any string, so the regex could be as follows:

```plaintext
Ident = r'(?P<Ident>[a-zA-Z_][a-zA-Z_0-9]*)'
```

The above selectors roughly correspond to their CSS counterparts (http://www.w3.org/TR/CSS21/selector.html)

Attributes and values

- Attributes are any valid (settable) property for the artist in question.
- Values are any valid value for the property (Usually a string, or number).

Parsing

Parsing would consist of breaking the stylesheet into tokens (the python cookbook gives a nice tokenizing recipe on page 66), applying the syntax rules and constructing a Tree. This requires defining the grammar of the stylesheet (again, we can borrow from CSS) and writing a parser. Happily, there is a recipe for this in the python cookbook as well.

Visitor pattern for matplotlib figure

In order to apply the stylesheet rules to the relevant artists, we need to ‘visit’ each artist in a figure and apply the relevant rule. Here is a visitor class (again, thanks to python cookbook), where each node would be
an artist in the figure. A `visit_` method would need to be implemented for each `mpl` artist, to handle the different properties for each

```python
class Visitor:
    def visit(self, node):
        name = 'visit_' + type(node).__name__
        meth = getattr(self, name, None)
        if meth is None:
            raise NotImplemented
        return meth(node)
```

An evaluator class would then take the stylesheet rules and implement the visitor on each one of them.

### 84.16.6 Backward compatibility

Implementing a separate Style class would break backward compatibility as many get/set methods on an artist would become redundant. While it would be possible to alter these methods to hook into the Style class (stored as a property against the artist), I would be in favor of simply removing them to both neaten/simplify the codebase and to provide a simple, uncluttered API...

### 84.16.7 Alternatives

No alternatives, but some of the ground covered here overlaps with MEP25, which may assist in this development.

### 84.16.8 Appendix

Matplotlib primitives

This will form the initial selectors which stylesheets can use.

- Line2D
- Text
- AxesImage
- FigureImage
- Patch

### 84.17 MEP27: decouple pyplot from backends

backend-refactor-wx

84.17.3 Abstract

This MEP refactors the backends to give a more structured and consistent API, removing generic code and consolidate existing code. To do this we propose splitting:

1. `FigureManagerBase` and its derived classes into the core functionality class `FigureManager` and a backend specific class `WindowBase` and

2. `ShowBase` and its derived classes into `Gcf.show_all` and `MainLoopBase`.

84.17.4 Detailed description

This MEP aims to consolidate the backends API into one single uniform API, removing generic code out of the backend (which includes `_pylab_helpers` and `Gcf`), and push code to a more appropriate level in matplotlib. With this we automatically remove inconsistencies that appear in the backends, such as `FigureManagerBase.resize(w, h)` which sometimes sets the canvas, and other times set the entire window to the dimensions given, depending on the backend.

Two main places for generic code appear in the classes derived from `FigureManagerBase` and `ShowBase`.

1. `FigureManagerBase` has **three** jobs at the moment:
(a) The documentation describes it as a ‘‘Helper class for pyplot mode, wraps everything up into a neat bundle’’

(b) But it doesn’t just wrap the canvas and toolbar, it also does all of the windowing tasks itself. The conflation of these two tasks gets seen the best in the following line: `python self.set_window_title("Figure %d" % num)` This combines backend specific code `self.set_window_title(title)` with matplotlib generic code `title = "Figure %d" % num`.

(c) Currently the backend specific subclass of FigureManager decides when to end the mainloop. This also seems very wrong as the figure should have no control over the other figures.

2. ShowBase has two jobs:

   (a) It has the job of going through all figure managers registered in `_pylab_helpers.Gcf` and telling them to show themselves.

   (b) And secondly it has the job of performing the backend specific mainloop to block the main programme and thus keep the figures from dying.

84.17.5 Implementation

The description of this MEP gives us most of the solution:

1. To remove the windowing aspect out of FigureManagerBase letting it simply wrap this new class along with the other backend classes. Create a new WindowBase class that can handle this functionality, with pass-through methods (:arrow_right:) to WindowBase. Classes that subclass WindowBase should also subclass the GUI specific window class to ensure backward compatibility (manager.window == manager.window).

2. Refactor the mainloop of ShowBase into MainLoopBase, which encapsulates the end of the loop as well. We give an instance of MainLoop to FigureManager as a key unlock the exit method (requiring all keys returned before the loop can die). Note this opens the possibility for multiple backends to run concurrently.

3. Now that FigureManagerBase has no backend specifics in it, to rename it to FigureManager, and move to a new file backend_managers.py noting that:

   (a) This allows us to break up the conversion of backends into separate PRs as we can keep the existing FigureManagerBase class and its dependencies intact.

   (b) and this also anticipates MEP22 where the new NavigationBase has morphed into a backend independent ToolManager.

**84.17.6 Future compatibility**

As eluded to above when discussing MEP 22, this refactor makes it easy to add in new generic features. At the moment, MEP 22 has to make ugly hacks to each class extending from FigureManagerBase. With this code, this only needs to get made in the single FigureManager class. This also makes the later deprecation of NavigationToolbar2 very straightforward, only needing to touch the single FigureManager class.

MEP 23 makes for another use case where this refactored code will come in very handy.

**84.17.7 Backward compatibility**

As we leave all backend code intact, only adding missing methods to existing classes, this should work seamlessly for all use cases. The only difference will lie for backends that used FigureManager.resize to resize the canvas and not the window, due to the standardisation of the API.

I would envision that the classes made obsolete by this refactor get deprecated and removed on the same timetable as NavigationToolbar2, also note that the change in call signature to the FigureCanvasWx constructor, while backward compatible, I think the old (imho ugly style) signature should get deprecated and removed in the same manner as everything else.
### 84.17.8 Alternatives

If there were any alternative solutions to solving the same problem, they should be discussed here, along with a justification for the chosen approach.

### 84.17.9 Questions

Mdehoon: Can you elaborate on how to run multiple backends concurrently?

OceanWolf: @mdehoon, as I say, not for this MEP, but I see this MEP opens it up as a future possibility. Basically the `MainLoopBase` class acts a per backend `Gcf`, in this MEP it tracks the number of figures open per backend, and manages the mainloops for those backends. It closes the backend specific mainloop when it detects that no figures remain open for that backend. Because of this I imagine that with only a small amount of tweaking that we can do full-multi-backend matplotlib. No idea yet why one would want to, but I leave the possibility there in `MainLoopBase`. With all the backend-code specifics refactored out of `FigureManager` also aids in this, one manager to rule them (the backends) all.

Mdehoon: @OceanWolf, OK, thanks for the explanation. Having a uniform API for the backends is very important for the maintainability of matplotlib. I think this MEP is a step in the right direction.
Matplotlib only uses BSD compatible code. If you bring in code from another project make sure it has a PSF, BSD, MIT or compatible license (see the Open Source Initiative licenses page for details on individual licenses). If it doesn’t, you may consider contacting the author and asking them to relicense it. GPL and LGPL code are not acceptable in the main code base, though we are considering an alternative way of distributing L/GPL code through an separate channel, possibly a toolkit. If you include code, make sure you include a copy of that code’s license in the license directory if the code’s license requires you to distribute the license with it. Non-BSD compatible licenses are acceptable in matplotlib toolkits (e.g., basemap), but make sure you clearly state the licenses you are using.

85.1 Why BSD compatible?

The two dominant license variants in the wild are GPL-style and BSD-style. There are countless other licenses that place specific restrictions on code reuse, but there is an important difference to be considered in the GPL and BSD variants. The best known and perhaps most widely used license is the GPL, which in addition to granting you full rights to the source code including redistribution, carries with it an extra obligation. If you use GPL code in your own code, or link with it, your product must be released under a GPL compatible license. i.e., you are required to give the source code to other people and give them the right to redistribute it as well. Many of the most famous and widely used open source projects are released under the GPL, including linux, gcc, emacs and sage.

The second major class are the BSD-style licenses (which includes MIT and the python PSF license). These basically allow you to do whatever you want with the code: ignore it, include it in your own open source project, include it in your proprietary product, sell it, whatever. python itself is released under a BSD compatible license, in the sense that, quoting from the PSF license page:

There is no GPL-like "copyleft" restriction. Distributing binary-only versions of Python, modified or not, is allowed. There is no requirement to release any of your source code. You can also write extension modules for Python and provide them only in binary form.

Famous projects released under a BSD-style license in the permissive sense of the last paragraph are the BSD operating system, python and TeX.

There are several reasons why early matplotlib developers selected a BSD compatible license. matplotlib is a python extension, and we choose a license that was based on the python license (BSD compatible).
Also, we wanted to attract as many users and developers as possible, and many software companies will not use GPL code in software they plan to distribute, even those that are highly committed to open source development, such as enthought, out of legitimate concern that use of the GPL will “infect” their code base by its viral nature. In effect, they want to retain the right to release some proprietary code. Companies and institutions who use matplotlib often make significant contributions, because they have the resources to get a job done, even a boring one. Two of the matplotlib backends (FLTK and WX) were contributed by private companies. The final reason behind the licensing choice is compatibility with the other python extensions for scientific computing: ipython, numpy, scipy, the enthought tool suite and python itself are all distributed under BSD compatible licenses.
As discussed at length elsewhere [insert links], jet is an empirically bad color map and should not be the default color map. Due to the position that changing the appearance of the plot breaks backward compatibility, this change has been put off for far longer than it should have been. In addition to changing the default color map we plan to take the chance to change the default color-cycle on plots and to adopt a different color map for filled plots (imshow, pcolor, contourf, etc) and for scatter like plots.

### 86.1 Default Heat Map Colormap

The choice of a new color map is fertile ground to bike-shedding (“No, it should be _this_ color”) so we have a proposed set criteria (via Nathaniel Smith) to evaluate proposed color maps.

- it should be a sequential colormap, because diverging colormaps are really misleading unless you know where the “center” of the data is, and for a default colormap we generally won’t.
- it should be perceptually uniform, i.e., human subjective judgments of how far apart nearby colors are should correspond as linearly as possible to the difference between the numerical values they represent, at least locally.
- it should have a perceptually uniform luminance ramp, i.e. if you convert to greyscale it should still be uniform. This is useful both in practical terms (greyscale printers are still a thing!) and because luminance is a very strong and natural cue to magnitude.
- it should also have some kind of variation in hue, because hue variation is a really helpful additional cue to perception, having two cues is better than one, and there’s no reason not to do it.
- the hue variation should be chosen to produce reasonable results even for viewers with the more common types of colorblindness. (Which rules out things like red-to-green.)
- For bonus points, it would be nice to choose a hue ramp that still works if you throw away the luminance variation, because then we could use the version with varying luminance for 2d plots, and the version with just hue variation for 3d plots. (In 3d plots you really want to reserve the luminance channel for lighting/shading, because your brain is really good at extracting 3d shape from luminance variation. If the 3d surface itself has massively varying luminance then this screws up the ability to see shape.)
- Not infringe any existing IP
86.1.1 Example script

86.1.2 Proposed Colormaps

86.2 Default Scatter Colormap

For heat-map like applications it can be desirable to cover as much of the luminence scale as possible, however when color mapping markers, having markers too close to white can be a problem. For that reason we propose using a different (but maybe related) color map to the heat map for marker-based. The design parameters are the same as above, only with a more limited luminence variation.

86.2.1 Example script

```python
import numpy as np
import matplotlib.pyplot as plt
np.random.seed(1234)
fig, (ax1, ax2) = plt.subplots(1, 2)
N = 50
x = np.random.rand(N)
y = np.random.rand(N)
colors = np.random.rand(N)
area = np.pi * (15 * np.random.rand(N))**2  # 0 to 15 point radiuses
ax1.scatter(x, y, s=area, c=colors, alpha=0.5)
X,Y = np.meshgrid(np.arange(0, 2*np.pi, .2),
                 np.arange(0, 2*np.pi, .2))
U = np.cos(X)
V = np.sin(Y)
Q = ax2.quiver(X, Y, U, V, units='width')
qd = np.random.rand(np.prod(X.shape))
Q.set_array(qd)
```

86.2.2 Proposed Colormaps

86.3 Color Cycle / Qualitative color map

When plotting lines it is frequently desirable to plot multiple lines or artists which need to be distinguishable, but there is no inherent ordering.
86.3.1 Example script

```python
import numpy as np
import matplotlib.pyplot as plt

fig, (ax1, ax2) = plt.subplots(1, 2)

x = np.linspace(0, 1, 10)

for j in range(10):
    ax1.plot(x, x * j)

th = np.linspace(0, 2*np.pi, 1024)
for j in np.linspace(0, np.pi, 10):
    ax2.plot(th, np.sin(th + j))

ax2.set_xlim(0, 2*np.pi)
```

**88.4 api example code: collections_demo.py**
size will be set in plot units, not data units. Their positions
will be set in data units by using the "offsets" and "transOffset"
kwargs of the LineCollection and PolyCollection.

The third subplot will make regular polygons, with the same
type of scaling and positioning as in the first two.

The last subplot illustrates the use of "offsets=(xo,yo)",
that is, a single tuple instead of a list of tuples, to generate
successively offset curves, with the offset given in data
units. This behavior is available only for the LineCollection.

```
import matplotlib.pyplot as plt
from matplotlib import collections, colors, transforms
import numpy as np

nverts = 50
npts = 100

# Make some spirals
r = np.arange(nverts)
theta = np.linspace(0, 2*np.pi, nverts)
xx = r * np.sin(theta)
yy = r * np.cos(theta)
spiral = list(zip(xx, yy))

# Make some offsets
rs = np.random.RandomState([12345678])
xo = rs.randn(npts)
yo = rs.randn(npts)
xyo = list(zip(xo, yo))

# Make a list of colors cycling through the default series.
colors = [colors.to_rgba(c)
for c in plt.rcParams['axes.prop_cycle'].by_key()['color']]

fig, axes = plt.subplots(2, 2)
fig.subplots_adjust(top=0.92, left=0.07, right=0.97,
hspace=0.3, wspace=0.3)

88.7 api example code: compound_path.py
**Compound path**

Make a compound path -- in this case two simple polygons, a rectangle and a triangle. Use `CLOSEPOLY` and `MOVETO` for the different parts of the compound path

```python
import numpy as np
from matplotlib.path import Path
from matplotlib.patches import PathPatch
import matplotlib.pyplot as plt

vertices = []
codes = []

codes = [Path.MOVETO] + [Path.LINETO]*3 + [Path.CLOSEPOLY]
vertices = [(1, 1), (1, 2), (2, 2), (2, 1), (0, 0)]

codes += [Path.MOVETO] + [Path.LINETO]*2 + [Path.CLOSEPOLY]
vertices += [(4, 4), (5, 5), (5, 4), (0, 0)]

vertices = np.array(vertices, float)
path = Path(vertices, codes)

pathpatch = PathPatch(path, facecolor='None', edgecolor='green')

fig, ax = plt.subplots()
ax.add_patch(pathpatch)
ax.set_title('A compound path')

ax.dataLim.update_from_data_xy(vertices)
ax.autoscale_view()

plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
This example showcases the Hammer projection by alleviating many features of matplotlib.

    # A (possibly non-linear) projection on the (already scaled) data
    
    # There are three important coordinate spaces going on here:
    #
    # 1. Data space: The space of the data itself
    #
    # 2. Axes space: The unit rectangle (0, 0) to (1, 1)
    #    covering the entire plot area.
    #
    # 3. Display space: The coordinates of the resulting image,
    #    often in pixels or dpi/inch.
    
    # This function makes heavy use of the Transform classes in
    # ``lib/matplotlib/transforms.py``. For more information, see
    # the inline documentation there.
    
    # The goal of the first two transformations is to get from the
    # data space (in this case longitude and latitude) to axes
    # space. It is separated into a non-affine and affine part so
    # that the non-affine part does not have to be recomputed when
    # a simple affine change to the figure has been made (such as
    # resizing the window or changing the dpi).
    
    # 1) The core transformation from data space into
    # rectilinear space defined in the HammerTransform class.
    self.transProjection = self._get_core_transform(self.RESOLUTION)
    
    # 2) The above has an output range that is not in the unit
    # rectangle, so scale and translate it so it fits correctly
    # within the axes. The peculiar calculations of xscale and
    # yscale are specific to a Aitoff-Hammer projection, so don't
    # worry about them too much.
    self.transAffine = self._get_affine_transform()
    
    # 3) This is the transformation from axes space to display
    # space.
    self.transAxes = BboxTransformTo(self.bbox)
    
    # Now put these 3 transforms together -- from data all the way
    # to display coordinates. Using the '+' operator, these
    # transforms will be applied "in order". The transforms are
    # automatically simplified, if possible, by the underlying
    # transformation framework.
    self.transData =
        self.transProjection +
        self.transAffine +

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
This example showcases how to create a custom scale, by implementing the scaling use for latitude data in a Mercator Projection.

```python
from __future__ import unicode_literals
import numpy as np
from numpy import ma
from matplotlib import scale as mscale
from matplotlib import transforms as mtransforms
from matplotlib.ticker import Formatter, FixedLocator
from matplotlib import rcParams

# BUG: this example fails with any other setting of axisbelow
rcParams['axes.axisbelow'] = False
```
class MercatorLatitudeScale(mscale.ScaleBase):
    
    Scales data in range -\pi/2 to \pi/2 (-90 to 90 degrees) using the system used to scale latitudes in a Mercator projection.

    The scale function:
    \[
    \ln(\tan(y) + \sec(y))
    \]

    The inverse scale function:
    \[
    \arctan(\sinh(y))
    \]

    Since the Mercator scale tends to infinity at +/- 90 degrees, there is user-defined threshold, above and below which nothing will be plotted. This defaults to +/- 85 degrees.

    source:
    http://en.wikipedia.org/wiki/Mercator_projection

    # The scale class must have a member `name` that defines the string used to select the scale. For example, `gca().set_yscale("mercator")` would be used to select this scale.
    name = 'mercator'

def __init__(self, axis, **kwargs):
    
    Any keyword arguments passed to `set_xscale` and `set_yscale` will be passed along to the scale's constructor.

    thresh: The degree above which to crop the data.

    mscale.ScaleBase.__init__(self)
    thresh = kwargs.pop("thresh", np.radians(85))
    if thresh >= np.pi / 2.0:
        raise ValueError("thresh must be less than pi/2")
    self.thresh = thresh

def get_transform(self):
    
    Override this method to return a new instance that does the actual transformation of the data.

    The MercatorLatitudeTransform class is defined below as a nested class of this one.

    return self.MercatorLatitudeTransform(self.thresh)

def set_default_locators_and_formatters(self, axis):
    

Override to set up the locators and formatters to use with the scale. This is only required if the scale requires custom locators and formatters. Writing custom locators and formatters is rather outside the scope of this example, but there are many helpful examples in ``ticker.py``.

In our case, the Mercator example uses a fixed locator from -90 to 90 degrees and a custom formatter class to put convert the radians to degrees and put a degree symbol after the value::

```python
class DegreeFormatter(Formatter):
    def __call__(self, x, pos=None):
        # ° : degree symbol
        return "%d\u00b0" % (np.degrees(x))
```

```python
axis.set_major_locator(FixedLocator(np.radians(np.arange(-90, 90, 10))))
axis.set_major_formatter(DegreeFormatter())
axis.set_minor_formatter(DegreeFormatter())
```

```python
def limit_range_for_scale(self, vmin, vmax, minpos):
    """
    Override to limit the bounds of the axis to the domain of the transform. In the case of Mercator, the bounds should be limited to the threshold that was passed in. Unlike the autoscaling provided by the tick locators, this range limiting will always be adhered to, whether the axis range is set manually, determined automatically or changed through panning and zooming.
    """

    return max(vmin, -self.thresh), min(vmax, self.thresh)
```

```python
class MercatorLatitudeTransform(mtransforms.Transform):
    # There are two value members that must be defined.
    # ``input_dims`` and ``output_dims`` specify number of input
    # dimensions and output dimensions to the transformation.
    # These are used by the transformation framework to do some
    # error checking and prevent incompatible transformations from
    # being connected together. When defining transforms for a
    # scale, which are, by definition, separable and have only one
    # dimension, these members should always be set to 1.
    input_dims = 1
    output_dims = 1
    is_separable = True

    def __init__(self, thresh):
        mtransforms.Transform.__init__(self)
        self.thresh = thresh

    def transform_non_affine(self, a):
        """
        This transform takes an N\times1 ``numpy`` array and returns a
```
transformed copy. Since the range of the Mercator scale is limited by the user-specified threshold, the input array must be masked to contain only valid values. `matplotlib` will handle masked arrays and remove the out-of-range data from the plot. Importantly, the `transform` method *must* return an array that is the same shape as the input array, since these values need to remain synchronized with values in the other dimension.

```python
masked = ma.masked_where((a < -self.thresh) | (a > self.thresh), a)
if masked.mask.any():
    return ma.log(np.abs(ma.tan(masked) + 1.0 / ma.cos(masked)))
else:
    return np.log(np.abs(np.tan(a) + 1.0 / np.cos(a)))

def inverted(self):
    ""
    Override this method so matplotlib knows how to get the inverse transform for this transform.
    ""
    return MercatorLatitudeScale.InvertedMercatorLatitudeTransform(self.thresh)
```

```python
class InvertedMercatorLatitudeTransform(mtransforms.Transform):
    input_dims = 1
    output_dims = 1
    is_separable = True

    def __init__(self, thresh):
        mtransforms.Transform.__init__(self)
        self.thresh = thresh

    def transform_non_affine(self, a):
        return np.arctan(np.sinh(a))

    def inverted(self):

****
============
Date tick labels
============

Show how to make date plots in matplotlib using date tick locators and formatters. See major_minor_demo1.py for more information on controlling major and minor ticks.

All matplotlib date plotting is done by converting date instances into days since the 0001-01-01 UTC. The conversion, tick locating and formatting is done behind the scenes so this is most transparent to
The dates module provides several converter functions date2num and num2date.

```python
import datetime
import numpy as np
import matplotlib.pyplot as plt
import matplotlib.dates as mdates
import matplotlib.cbook as cbook

years = mdates.YearLocator()  # every year
months = mdates.MonthLocator()  # every month
yearsFmt = mdates.DateFormatter('%Y')

# load a numpy record array from yahoo csv data with fields date, open, close, volume, adj_close from the mpl-data/example directory.
# The record array stores python datetime.date as an object array in
# the date column
datafile = cbook.get_sample_data('goog.npy')
try:
    # Python3 cannot load python2 .npy files with datetime(object) arrays
    # unless the encoding is set to bytes. However this option was
    # not added until numpy 1.10 so this example will only work with
    # python 2 or with numpy 1.10 and later.
    r = np.load(datafile, encoding='bytes').view(np.recarray)
except TypeError:
    r = np.load(datafile).view(np.recarray)

fig, ax = plt.subplots()
ax.plot(r.date, r.adj_close)

# format the ticks
ax.xaxis.set_major_locator(years)
ax.xaxis.set_major_formatter(yearsFmt)
ax.xaxis.set_minor_locator(months)
datemin = datetime.date(r.date.min().year, 1, 1)
datemax = datetime.date(r.date.max().year + 1, 1, 1)
ax.set_xlim(datemin, datemax)

# format the coords message box
def price(x):
    return '$%1.2f' % x
ax.format_xdata = mdates.DateFormatter('%Y-%m-%d')
ax.format_ydata = price
ax.grid(True)

# rotates and right aligns the x labels, and moves the bottom of the
# axes up to make room for them
fig.autofmt_xdate()
```
88.11 api example code: date_index_formatter.py

```python
from __future__ import print_function
import numpy as np
import matplotlib.pyplot as plt
import matplotlib.mlab as mlab
import matplotlib.cbook as cbook
import matplotlib.ticker as ticker

datafile = cbook.get_sample_data('aapl.csv', asfileobj=False)
print('loading %s' % datafile)
r = mlab.csv2rec(datafile)
r.sort()
r = r[-30:]  # get the last 30 days
```

When plotting time series, e.g., financial time series, one often wants to leave out days on which there is no data, i.e. weekends. The example below shows how to use an 'index formatter' to achieve the desired plot.
# first we'll do it the default way, with gaps on weekends
fig, axes = plt.subplots(ncols=2, figsize=(8, 4))
ax = axes[0]
ax.plot(r.date, r.adj_close, 'o-')
ax.set_title("Default")
fig.autofmt_xdate()

# next we'll write a custom formatter
N = len(r)
ind = np.arange(N)  # the evenly spaced plot indices

def format_date(x, pos=None):
    thisind = np.clip(int(x + 0.5), 0, N - 1)
    return r.date[thisind].strftime('%Y-%m-%d')

ax = axes[1]
ax.plot(ind, r.adj_close, 'o-')
ax.xaxis.set_major_formatter(ticker.FuncFormatter(format_date))
ax.set_title("Custom tick formatter")
fig.autofmt_xdate()

plt.show()
Affine transform of an image

For the backends that support draw_image with optional affine transform (e.g., agg, ps backend), the image of the output should have its boundary match the dashed yellow rectangle.

```python
import numpy as np
import matplotlib.mlab as mlab
import matplotlib.pyplot as plt
import matplotlib.transforms as mtransforms

def get_image:
    delta = 0.25
    x = y = np.arange(-3.0, 3.0, delta)
    X, Y = np.meshgrid(x, y)
    Z1 = mlab.bivariate_normal(X, Y, 1.0, 1.0, 0.0, 0.0)
    Z2 = mlab.bivariate_normal(X, Y, 1.5, 0.5, 1, 1)
```
$Z = Z_2 - Z_1 \quad \# \textit{difference of Gaussians}$

```
return Z
```

def do_plot(ax, Z, transform):
    im = ax.imshow(Z, interpolation='none',
                    origin='lower',
                    extent=[-2, 4, -3, 2], clip_on=True)

    trans_data = transform + ax.transData
    im.set_transform(trans_data)

    # display intended extent of the image
    x1, x2, y1, y2 = im.get_extent()
    ax.plot([x1, x2, x2, x1, x1], [y1, y1, y2, y2, y1], 'y--',
            transform=trans_data)
    ax.set_xlim(-5, 5)
    ax.set_ylim(-4, 4)

# prepare image and figure
fig, ((ax1, ax2), (ax3, ax4)) = plt.subplots(2, 2)
Z = get_image()

# image rotation
do_plot(ax1, Z, mtransforms.Affine2D().rotate_deg(30))

# image skew
do_plot(ax2, Z, mtransforms.Affine2D().skew_deg(30, 15))

# scale and reflection
do_plot(ax3, Z, mtransforms.Affine2D().scale(-1, .5))

# everything and a translation
    do_plot(ax4, Z, mtransforms.Affine2D().
            rotate_deg(30).skew_deg(30, 15).scale(-1, .5).translate(.5, -1))
plt.show()
This example draws donuts (miam!) using Path and Patches.

```python
import numpy as np
import matplotlib.path as mpath
import matplotlib.patches as mpatches
import matplotlib.pyplot as plt

def wise(v):
    if v == 1:
        return "CCW"
    else:
        return "CW"

def make_circle(r):
```

Mmm, donuts!
import numpy as np
import matplotlib.pyplot as plt
from matplotlib.path import Path
from matplotlib.patches import PathPatch

r = 1

def make_circle(radius):
    t = np.arange(0, np.pi * 2.0, 0.01)
    t = t.reshape((len(t), 1))
    x = r * np.cos(t)
    y = r * np.sin(t)
    return np.hstack((x, y))

Path = mpath.Path

fig, ax = plt.subplots()
inside_vertices = make_circle(0.5)
outside_vertices = make_circle(1.0)
codes = np.ones(len(inside_vertices), dtype=mpath.Path.code_type) * mpath.Path.LINETO
codes[0] = mpath.Path.MOVETO

for i, (inside, outside) in enumerate(((1, 1), (1, -1), (-1, 1), (-1, -1))):
    vertices = np.concatenate((outside_vertices[::outside], inside_vertices[::inside]))
    vertices[:, 0] += i * 2.5
    all_codes = np.concatenate((codes, codes))
    path = mpath.Path(vertices, all_codes)
    patch = mpatches.PathPatch(path, facecolor='#885500', edgecolor='black')
    ax.add_patch(patch)
    ax.annotate("Outside \( %s \), Inside \( %s \)" % (wise(outside), wise(inside)), (i * 2.5, -1.5), va="top", ha="center")

ax.set_xlim(-2, 10)
ax.set_ylim(-3, 2)
ax.set_title('Mmm, donuts!')
ax.set_aspect(1.0)
plt.show()
Demo to show use of the engineering Formatter.

```python
import matplotlib.pyplot as plt
import numpy as np
from matplotlib.ticker import EngFormatter

prng = np.random.RandomState(123)

fig, ax = plt.subplots()
ax.set_xscale('log')
formatter = EngFormatter(unit='Hz')
ax.xaxis.set_major_formatter(formatter)

xs = np.logspace(1, 9, 100)
ys = (0.8 + 0.4 * prng.uniform(size=100)) * np.log10(xs)**2
```
ax.plot(xs, ys)
plt.show()

Hatch-filled histograms
========================
This example showcases the hatching capabilities of matplotlib by plotting various histograms.

```python
import itertools
from collections import OrderedDict
from functools import partial
import numpy as np
import matplotlib.pyplot as plt
import matplotlib.ticker as mticker
from cycler import cycler
from six.moves import zip

def filled_hist(ax, edges, values, bottoms=None, orientation='v', **kwargs):
    """
    Draw a histogram as a stepped patch.
    Extra kwargs are passed through to `fill_between`
    Parameters
    ----------
    ax : Axes
        The axes to plot to
    edges : array
        A length n+1 array giving the left edges of each bin and the right edge of the last bin.
    values : array
        A length n array of bin counts or values
    bottoms : scalar or array, optional
        A length n array of the bottom of the bars. If None, zero is used.
    orientation : {'v', 'h'}
        Orientation of the histogram. 'v' (default) has the bars increasing in the positive y-direction.
    Returns
    -------
    ret : PolyCollection
        Artist added to the Axes
    """
    print(orientation)
    if orientation not in set('hv'):
        raise ValueError("orientation must be in {{'h', 'v'}} " "not {o}".format(o=orientation))
```

88.15. api example code: filled_step.py
kwargs.setdefault('step', 'post')
edges = np.asarray(edges)
values = np.asarray(values)
if len(edges) - 1 != len(values):
    raise ValueError('Must provide one more bin edge than value not: ' 'len(edges): {lb} len(values): {lv}'.format(
    lb=len(edges), lv=len(values)))

if bottoms is None:
    bottoms = np.zeros_like(values)
if np.isscalar(bottoms):
    bottoms = np.ones_like(values) * bottoms

values = np.r_[values, values[-1]]
bottoms = np.r_[bottoms, bottoms[-1]]
if orientation == 'h':
    return ax.fill_betweenx(edges, values, bottoms,
                            **kwargs)
elif orientation == 'v':
    return ax.fill_between(edges, values, bottoms,
                            **kwargs)
else:
    raise AssertionError("you should never be here")

def stack_hist(ax, stacked_data, sty_cycle, bottoms=None, hist_func=None, labels=None, plot_func=None, plot_kwargs=None):
    ""
    ax : axes.Axes
        The axes to add artists too

estacked_data : array or Mapping
    A (N, M) shaped array. The first dimension will be iterated over to
    compute histograms row-wise

stystyle : Cycler or operable of dict
    Style to apply to each set

bottoms : array, optional
    The initial positions of the bottoms, defaults to 0

hist_func : callable, optional
    Must have signature 'bin_vals, bin_edges = f(data)'.
    'bin_edges' expected to be one longer than 'bin_vals'

labels : list of str, optional
    The label for each set.

    If not given and stacked data is an array defaults to 'default set {n}''

    If stacked_data is a mapping, and labels is None, default to the keys
If `stacked_data` is a mapping and `labels` is given then only the columns listed by be plotted.

`plot_func` : callable, optional
Function to call to draw the histogram must have signature:

```python
ret = plot_func(ax, edges, top, bottoms=bottoms,
               label=label, **kwargs)
```

`plot_kwargs` : dict, optional
Any extra kwargs to pass through to the plotting function. This will be the same for all calls to the plotting function and will over-ride the values in cycle.

Returns
-------
`arts` : dict
Dictionary of artists keyed on their labels

# deal with default binning function
```python
if hist_func is None:
    hist_func = np.histogram
```

# deal with default plotting function
```python

===================================
Using a ttf font file in matplotlib
===================================

Although it is usually not a good idea to explicitly point to a single
ttf file for a font instance, you can do so using the
font_manager.FontProperties fname argument (for a more flexible
solution, see the font_family_rc.py and fonts_demo.py examples).

import sys
import os
import matplotlib.font_manager as fm
import matplotlib.pyplot as plt

fig, ax = plt.subplots()
ax.plot([1, 2, 3])

if sys.platform == 'win32':
    fpath = 'C:\Windows\Fonts\Tahoma.ttf'
elif sys.platform.startswith('linux'):
    basedir = '/usr/share/fonts/truetype'
    fonts = ['freefont/FreeSansBoldOblique.ttf',
             'ttf-liberation/LiberationSans-BoldItalic.ttf',
             'msttcorefonts/Comic_Sans_MS.ttf']
    for fpath in fonts:
        if os.path.exists(os.path.join(basedir, fpath)):
            break
else:
    fpath = '/Library/Fonts/Tahoma.ttf'

if os.path.exists(fpath):
    prop = fm.FontProperties(fname=fpath)
    fname = os.path.split(fpath)[1]
    ax.set_title('this is a special font: %s' % fname, fontproperties=prop)

    ax.set_title('Demo fails--cannot find a demo font')
ax.set_xlabel('This is the default font')

plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
This example shows how to use a path patch to draw a bunch of rectangles. The technique of using lots of Rectangle instances, or the faster method of using PolyCollections, were implemented before we had proper paths with moveto/lineto, closepoly etc in mpl. Now that we have them, we can draw collections of regularly shaped objects with homogeneous properties more efficiently with a PathCollection. This example makes a histogram -- its more work to set up the vertex arrays at the outset, but it should be much faster for large numbers of objects.

```python
import numpy as np
import matplotlib.pyplot as plt
import matplotlib.patches as patches
import matplotlib.path as path

fig, ax = plt.subplots()
```
# histogram our data with numpy
data = np.random.randn(1000)
n, bins = np.histogram(data, 50)

# get the corners of the rectangles for the histogram
left = np.array(bins[:-1])
right = np.array(bins[1:])
bottom = np.zeros(len(left))
top = bottom + n

# we need a (numrects x numsides x 2) numpy array for the path helper
# function to build a compound path
XY = np.array([[left, left, right, right], [bottom, top, top, bottom]]).T

# get the Path object
barpath = path.Path.make_compound_path_from_polys(XY)

# make a patch out of it
patch = patches.PathPatch(barpath)
ax.add_patch(patch)

# update the view limits
ax.set_xlim(left[0], right[-1])
ax.set_ylim(bottom.min(), top.max())

The default settings produce a diagram like this.
Flow Diagram of a Widget

- Widget A
- First 10%
- Second 20%
- Third 5%
- Fourth 15%
- Fifth 10%
- Hurray! 40%
- 60%
- 25%
The Sankey class

Demonstrate the Sankey class by producing three basic diagrams.

```python
import numpy as np
import matplotlib.pyplot as plt
from matplotlib.sankey import Sankey

# Example 1 -- Mostly defaults
# This demonstrates how to create a simple diagram by implicitly calling the
# Sankey.add() method and by appending finish() to the call to the class.
Sankey(flows=[0.25, 0.15, 0.60, -0.20, -0.15, -0.05, -0.50, -0.10],
      labels=['', '', '' , 'First', 'Second', 'Third', 'Fourth', 'Fifth'],
      orientations=[-1, 1, 0, 1, 1, 1, 0, -1]).finish()
plt.title("The default settings produce a diagram like this.")
```

# Notice:
# 1. Axes weren't provided when Sankey() was instantiated, so they were created automatically.
# 2. The scale argument wasn't necessary since the data was already normalized.
# 3. By default, the lengths of the paths are justified.
# Example 2
# This demonstrates:
# 1. Setting one path longer than the others
# 2. Placing a label in the middle of the diagram
# 3. Using the scale argument to normalize the flows
# 4. Implicitly passing keyword arguments to PathPatch()
# 5. Changing the angle of the arrow heads
# 6. Changing the offset between the tips of the paths and their labels
# 7. Formatting the numbers in the path labels and the associated unit
# 8. Changing the appearance of the patch and the labels after the figure is created

fig = plt.figure()
ax = fig.add_subplot(1, 1, 1, xticks=[], yticks=[],
                   title="Flow Diagram of a Widget")
sankey = Sankey(ax=ax, scale=0.01, offset=0.2, head_angle=180,
               format='%.0f', unit='%')
sankey.add(flows=[25, 0, 60, -10, -20, -5, -15, -10, -40],
          labels=['', '', '', 'First', 'Second', 'Third', 'Fourth',
               'Fifth', 'Hurray!'],
          orientations=[-1, 1, 0, 1, 1, 1, -1, -1, 0],
          pathlengths=[0.25, 0.25, 0.25, 0.25, 0.25, 0.25, 0.6, 0.25, 0.25],
          patchlabel="Widget

A")  # Arguments to matplotlib.patches.PathPatch()
diagrams = sankey.finish()
diagrams[0].texts[-1].set_color('r')
diagrams[0].text.set_fontweight('bold')

# Notice:
# 1. Since the sum of the flows is nonzero, the width of the trunk isn't uniform. If verbose.level is helpful (in matplotlibrc), a message is given in the terminal window.
# 2. The second flow doesn't appear because its value is zero. Again, if verbose.level is helpful, a message is given in the terminal window.

# Example 3
# This demonstrates:
# 1. Connecting two systems
# 2. Turning off the labels of the quantities
# 3. Adding a legend

fig = plt.figure()
ax = fig.add_subplot(1, 1, 1, xticks=[], yticks=[], title="Two Systems")
flows = [0.25, 0.15, 0.60, -0.10, -0.05, -0.25, -0.15, -0.10, -0.35]
sankey = Sankey(ax=ax, unit=None)
sankey.add(flows=flows, label='one',
         orientations=[-1, 1, 0, 1, 1, 1, -1, -1, 0])
sankey.add(flows=[-0.25, 0.15, 0.1], label='two',
         orientations=[-1, -1, -1], prior=0, connect=(0, 0))
diagrams = sankey.finish()
diagrams[-1].patch.set_hatch('/')
plt.legend(loc='best')

# Notice that only one connection is specified, but the systems form a circuit since: (1) the lengths of the paths are justified and (2) the orientation and ordering of the flows is mirrored.
plt.show()

plt.show()
This serves as an intensive exercise of matplotlib's transforms and custom projection API. This example produces a so-called SkewT-logP diagram, which is a common plot in meteorology for displaying vertical profiles of temperature. As far as matplotlib is concerned, the complexity comes from having X and Y axes that are not orthogonal. This is handled by including a skew component to the basic Axes transforms. Additional complexity comes in handling the fact that the upper and lower X-axes have different data ranges, which necessitates a bunch of custom classes for ticks, spines, and the axis to handle this.
from matplotlib import axes
import matplotlib.transforms as transforms
import matplotlib.axis as maxis

### 88.35 api example code: span_regions.py

![Using span_where](image-url)
Using `span_where`  
================  
Illustrate some helper functions for shading regions where a logical mask is True

See :meth:`matplotlib.collections.BrokenBarHCollection.span_where`

```python
import numpy as np
import matplotlib.pyplot as plt
import matplotlib.collections as collections

t = np.arange(0.0, 2, 0.01)
s1 = np.sin(2*np.pi*t)
s2 = 1.2*np.sin(4*np.pi*t)

fig, ax = plt.subplots()
ax.set_title('using span_where')
ax.plot(t, s1, color='black')
ax.axhline(0, color='black', lw=2)

collection = collections.BrokenBarHCollection.span_where(
    t, ymin=0, ymax=1, where=s1 > 0, facecolor='green', alpha=0.5)
ax.add_collection(collection)

collection = collections.BrokenBarHCollection.span_where(
    t, ymin=-1, ymax=0, where=s1 < 0, facecolor='red', alpha=0.5)
ax.add_collection(collection)

plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
```python
import numpy as np
import matplotlib.pyplot as plt

2086 Chapter 88. api Examples
```
fig, ax1 = plt.subplots()
t = np.arange(0.01, 10.0, 0.01)
s1 = np.exp(t)
ax1.plot(t, s1, 'b-')
ax1.set_xlabel('time (s)')
# Make the y-axis label, ticks and tick labels match the line color.
ax1.set_ylabel('exp', color='b')
ax1.tick_params(y, colors='b')

ax2 = ax1.twinx()
s2 = np.sin(2 * np.pi * t)
ax2.plot(t, s2, 'r-')
ax2.set_ylabel('sin', color='r')
ax2.tick_params(y, colors='r')

fig.tight_layout()
plt.show()

Keywords: python, matplotlib, pylab, example, codex (see Search examples)

88.37 api example code: unicode_minus.py

Using hyphen instead of Unicode minus
You can use the proper typesetting Unicode minus (see https://en.wikipedia.org/wiki/Plus_sign#Plus_sign) or the ASCII hyphen for minus, which some people prefer. The matplotlibrc param axes.unicode_minus controls the default behavior.

The default is to use the Unicode minus.

import numpy as np
import matplotlib
import matplotlib.pyplot as plt

matplotlib.rcParams['axes.unicode_minus'] = False
fig, ax = plt.subplots()
ax.plot(10*np.random.randn(100), 10*np.random.randn(100), 'o')
ax.set_title('Using hyphen instead of Unicode minus')
plt.show()
**Watermark image**

Use a PNG file as a watermark

```python
from __future__ import print_function
import numpy as np
import matplotlib.cbook as cbook
import matplotlib.image as image
import matplotlib.pyplot as plt

datafile = cbook.get_sample_data('logo2.png', asfileobj=False)
print('loading %s' % datafile)
im = image.imread(datafile)
im[:, :, -1] = 0.5  # set the alpha channel

fig, ax = plt.subplots()
ax.plot(np.random.rand(20), '-o', ms=20, lw=2, alpha=0.7, mfc='orange')
ax.grid()
```

88.38 api example code: watermark_image.py
fig.figimage(im, 10, 10, zorder=3)
plt.show()

Keywords: python, matplotlib, pylab, example, codex (see Search examples)

88.39 api example code: watermark_text.py

""
==============
Text watermark
==============

Use a Text as a watermark
""

import numpy as np
# import matplotlib
# matplotlib.use('Agg')

import matplotlib.pyplot as plt

fig, ax = plt.subplots()
ax.plot(np.random.rand(20), '-o', ms=20, lw=2, alpha=0.7, mfc='orange')
ax.grid()

# position bottom right
fig.text(0.95, 0.05, 'Property of MPL',
        fontsize=50, color='gray',
        ha='right', va='bottom', alpha=0.5)

plt.show()

 Demo of the floating axes.

This demo shows features of functions in floating_axes:
 * Using scatter function and bar function with changing the shape of the plot.
 * Using GridHelperCurveLinear to rotate the plot and set the boundary of the plot.
 * Using FloatingSubplot to create a subplot using the return value from GridHelperCurveLinear.
 * Making sector plot by adding more features to GridHelperCurveLinear.

Parasite axis demo

The following code is an example of a parasite axis. It aims to show a user how to plot multiple different values onto one single plot. Notice how in this example, par1 and par2 are both calling twinx meaning both are tied directly to the x-axis. From there, each of those two axis can behave separately from the each other, meaning they can take on separate values from themselves as well as the x-axis.

```python
from mpl_toolkits.axes_grid1 import host_subplot
import mpl_toolkits.axisartist as AA
import matplotlib.pyplot as plt

host = host_subplot(111, axes_class=AA.Axes)
plt.subplots_adjust(right=0.75)
par1 = host.twinx()
par2 = host.twinx()

offset = 60
new_fixed_axis = par2.get_grid_helper().new_fixed_axis
```

---

89.14 axes_grid example code: demo_parasite_axes2.py
par2.axis['right'] = new_fixed_axis(loc='right',
    axes=par2,
    offset=(offset, 0))

par2.axis['right'].toggle(all=True)

host.set_xlim(0, 2)
host.set_ylim(0, 2)

host.set_xlabel("Distance")
host.set_ylabel("Density")
par1.set_ylabel("Temperature")
par2.set_ylabel("Velocity")

p1, = host.plot([0, 1, 2], [0, 1, 2], label="Density")
p2, = par1.plot([0, 1, 2], [0, 3, 2], label="Temperature")
p3, = par2.plot([0, 1, 2], [50, 30, 15], label="Velocity")

par1.set_ylim(0, 4)
par2.set_ylim(1, 65)

host.legend()

host.axis['left'].label.set_color(p1.get_color())
par1.axis['right'].label.set_color(p2.get_color())
par2.axis['right'].label.set_color(p3.get_color())

90.1 color example code: color_cycle_default.py

Display the colors from the default prop_cycle.

```python
import numpy as np
import matplotlib.pyplot as plt

prop_cycle = plt.rcParams['axes.prop_cycle']
colors = prop_cycle.by_key()]['color']
```
lwbasis = plt.rcParams['lines.linewidth']
thin = float('%.1f' % (lwbasis / 2))
thick = lwbasis * 3

fig, axs = plt.subplots(nrows=2, ncols=2, sharex=True, sharey=True)
for icol in range(2):
    if icol == 0:
        lwx, lwy = thin, lwbasis
    else:
        lwx, lwy = lwbasis, thick
    for irow in range(2):
        for i, color in enumerate(colors):
            axs[irow, icol].axhline(i, color=color, lw=lwx)
            axs[irow, icol].axvline(i, color=color, lw=lwy)

axs[1, icol].set_facecolor('k')
axs[1, icol].xaxis.set_ticks(np.arange(0, 10, 2))
axs[0, icol].set_title('line widths (pts): %.1f, %.1f' % (lwx, lwy),
                        fontsize='medium')

for irow in range(2):
    axs[irow, 0].yaxis.set_ticks(np.arange(0, 10, 2))

fig.suptitle('Colors in the default prop_cycle', fontsize='large')
plt.show()

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
Demo of custom property-cycle settings to control colors and such for multi-line plots.

This example demonstrates two different APIs:

1. Setting the default rc-parameter specifying the property cycle. This affects all subsequent axes (but not axes already created).
2. Setting the property cycle for a specific axes. This only affects a single axes.

```python
from cycler import cycler
import numpy as np
import matplotlib.pyplot as plt

x = np.linspace(0, 2 * np.pi)
offsets = np.linspace(0, 2*np.pi, 4, endpoint=False)
# Create array with shifted-sine curve along each column
yy = np.transpose([np.sin(x + phi) for phi in offsets])

plt.rc('lines', linewidth=4)
plt.rc('axes', prop_cycle=(cycler('color', ['r', 'g', 'b', 'y']) +
```
```python
cycler('linestyle', ['-','--','::','-'])
fig, (ax0, ax1) = plt.subplots(nrows=2)
ax0.plot(yy)
ax0.set_title('Set default color cycle to rgb')

ax1.set_prop_cycle(cycler('color', ['c', 'm', 'y', 'k']) + cycler('lw', [1, 2, 3, 4]))
ax1.plot(yy)
ax1.set_title('Set axes color cycle to cmyk')

# Tweak spacing between subplots to prevent labels from overlapping
fig.subplots_adjust(hspace=0.3)
plt.show()
```

- Set1
- Set2
- Set3
- Vega10
- Vega20
- Vega20b
- Vega20c
Reference for colormaps included with Matplotlib.

This reference example shows all colormaps included with Matplotlib. Note that any colormap listed here can be reversed by appending "_r" (e.g., "pink_r"). These colormaps are divided into the following categories:

Sequential:
These colormaps are approximately monochromatic colormaps varying smoothly between two color tones---usually from low saturation (e.g. white) to high saturation (e.g. a bright blue). Sequential colormaps are ideal for representing most scientific data since they show a clear progression from low-to-high values.

Diverging:
These colormaps have a median value (usually light in color) and vary smoothly to two different color tones at high and low values. Diverging colormaps are ideal when your data has a median value that is significant (e.g. 0, such that positive and negative values are represented by different colors of the colormap).

Qualitative:
These colormaps vary rapidly in color. Qualitative colormaps are useful for choosing a set of discrete colors. For example:

```python
color_list = plt.cm.Set3(np.linspace(0, 1, 12))
```
gives a list of RGB colors that are good for plotting a series of lines on a dark background.

Miscellaneous:
- Colormaps that don’t fit into the categories above.

```python
import numpy as np
import matplotlib.pyplot as plt

# Have colormaps separated into categories:
# http://matplotlib.org/examples/color/colormaps_reference.html
cmaps = [('Perceptually Uniform Sequential',
          ['viridis', 'inferno', 'plasma', 'magma']),
        ('Sequential', ['Blues', 'BuGn', 'BuPu',
                        'GnBu', 'Greens', 'Greys', 'Oranges', 'OrRd',
                        'PuBu', 'PuBuGn', 'PuRd', ' Purples', 'RdPu',
                        'Reds', 'YlGn', 'YlGnBu', 'YlOrBr', 'YlOrRd']),
        ('Sequential (2)', ['afmhot', 'autumn', 'bone', 'cool',
                            'copper', 'gist_heat', 'gray', 'hot',
                            'pink', 'spring', 'summer', 'winter']),
        ('Diverging', ['BrBG', 'bwr', 'coolwarm', 'PiYG', 'PRGn', 'PuOr',
                        'RdBu', 'RdGy', 'RdYlBu', 'RdYlGn', 'Spectral',
                        'seismic']),

91.10 event_handling example code: pick_event_demo.py

[source code]
You can enable picking by setting the "picker" property of an artist (for example, a matplotlib Line2D, Text, Patch, Polygon, AxesImage, etc...)

There are a variety of meanings of the picker property

None - picking is disabled for this artist (default)

boolean - if True then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist

float - if picker is a number it is interpreted as an epsilon tolerance in points and the artist will fire off an event if it's data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, for example, the indices of the data within epsilon of the pick event

function - if picker is callable, it is a user supplied function which determines whether the artist is hit by the mouse event.

    hit, props = picker(artist, mouseevent)

to determine the hit test. If the mouse event is over the artist, return hit=True and props is a dictionary of properties you want added to the PickEvent attributes

After you have enabled an artist for picking by setting the "picker" property, you need to connect to the figure canvas pick_event to get pick callbacks on mouse press events. For example,

    def pick_handler(event):
        mouseevent = event.mouseevent
        artist = event.artist
        # now do something with this...

The pick event (matplotlib.backend_bases.PickEvent) which is passed to your callback is always fired with two attributes:

mouseevent - the mouse event that generate the pick event. The mouse event in turn has attributes like x and y (the coordinates in display space, such as pixels from left, bottom) and xdata, ydata (the coords in data space). Additionally, you can get information about which buttons were pressed, which keys were pressed, which Axes the mouse is over, etc. See matplotlib.backend_bases.MouseEvent for details.
artist - the matplotlib.artist that generated the pick event.

Additionally, certain artists like Line2D and PatchCollection may attach additional meta data like the indices into the data that meet the picker criteria (for example, all the points in the line that are within the specified epsilon tolerance)

The examples below illustrate each of these methods.

Demonstrate use of a log color scale in contourf

```
import matplotlib.pyplot as plt
import numpy as np
from numpy import ma
from matplotlib import colors, ticker, cm
from matplotlib.mlab import bivariate_normal
```
N = 100
x = np.linspace(-3.0, 3.0, N)
y = np.linspace(-2.0, 2.0, N)

X, Y = np.meshgrid(x, y)

# A low hump with a spike coming out of the top right.
# Needs to have z/colour axis on a log scale so we see both hump and spike.
# linear scale only shows the spike.
z = (bivariate_normal(X, Y, 0.1, 0.2, 1.0, 1.0)
    + 0.1 * bivariate_normal(X, Y, 1.0, 1.0, 0.0, 0.0))

# Put in some negative values (lower left corner) to cause trouble with logs:
z[:5, :5] = -1

# The following is not strictly essential, but it will eliminate
# a warning. Comment it out to see the warning.
z = ma.masked_where(z <= 0, z)

# Automatic selection of levels works; setting the
# log locator tells contourf to use a log scale:
fig, ax = plt.subplots()
    cs = ax.contourf(X, Y, z, locator=ticker.LogLocator(), cmap=cm.PuBu_r)

# Alternatively, you can manually set the levels
# and the norm:
    #lev_exp = np.arange(np.floor(np.log10(z.min()))-1),
    #np.ceil(np.log10(z.max()))+1))
    #levs = np.power(10, lev_exp)
    #cs = P.contourf(X, Y, z, levs, norm=colors.LogNorm())

# The 'extend' kwarg does not work yet with a log scale.
cbar = fig.colorbar(cs)

plt.show()
93.2 images_contours_and_fields example code: image_demo.py

```python
# Simple demo of the imshow function.

import matplotlib.pyplot as plt
import matplotlib.cbook as cbook

Show all different interpolation methods for imshow

```python
import matplotlib.pyplot as plt
import numpy as np

# from the docs:
# If interpolation is None, default to rc image.interpolation. See also
# the filternorm and filterrad parameters. If interpolation is 'none', then
# no interpolation is performed on the Agg, ps and pdf backends. Other
# backends will fall back to 'nearest'.
#
# http://matplotlib.org/api/pyplot_api.html#matplotlib.pyplot.imshow

methods = [None, 'none', 'nearest', 'bilinear', 'bicubic', 'spline16',
           'spline36', 'hanning', 'hamming', 'hermite', 'kaiser', 'quadric',
           'catrom', 'gaussian', 'bessel', 'mitchell', 'sinc', 'lanczos']

np.random.seed(0)
grid = np.random.rand(4, 4)

fig, axes = plt.subplots(3, 6, figsize=(12, 6),
                         subplot_kw={'xticks': [], 'yticks': []})

fig.subplots_adjust(hspace=0.3, wspace=0.05)
```

for ax, interp_method in zip(axes.flat, methods):
    ax.imshow(grid, interpolation=interp_method, cmap='viridis')
    ax.set_title(interp_method)
plt.show()
Displays the difference between interpolation = 'none' and interpolation = 'nearest'.

Interpolation = 'none' and interpolation = 'nearest' are equivalent when converting a figure to an image file, such as a PNG. Interpolation = 'none' and interpolation = 'nearest' behave quite differently, however, when converting a figure to a vector graphics file, such as a PDF. As shown, Interpolation = 'none' works well when a big image is scaled down, while interpolation = 'nearest' works well when a small image is blown up.

```python
import numpy as np
import matplotlib.pyplot as plt
import matplotlib.cbook as cbook
```
# Load big image
big_im_path = cbook.get_sample_data('necked_tensile_specimen.png')
big_im = plt.imread(big_im_path)

# Define small image
small_im = np.array([[0.25, 0.75, 1.0, 0.75], [0.1, 0.65, 0.5, 0.4],
                     [0.6, 0.3, 0.0, 0.2], [0.7, 0.9, 0.4, 0.6]])

# Create a 2x2 table of plots
fig, axes = plt.subplots(figsize=[8.0, 7.5], ncols=2, nrows=2)

axes[0, 0].imshow(big_im, interpolation='none')
axes[0, 1].imshow(big_im, interpolation='nearest')
axes[1, 0].imshow(small_im, interpolation='none')
axes[1, 1].imshow(small_im, interpolation='nearest')

fig.subplots_adjust(left=0.24, wspace=0.2, hspace=0.1,
                     bottom=0.05, top=0.86)

# Label the rows and columns of the table
fig.text(0.03, 0.645, 'Big Image
Scaled Down', ha='left')
fig.text(0.03, 0.225, 'Small Image
Blown Up', ha='left')
fig.text(0.383, 0.90, 'Interpolation = ' 'none''', ha='center')
fig.text(0.75, 0.90, 'Interpolation = ' 'nearest''', ha='center')

# If you were going to run this example on your local machine, you
# would save the figure as a PNG, save the same figure as a PDF, and
# then compare them. The following code would suffice.
txt = fig.text(0.452, 0.95, 'Saved as a PNG', fontsize=18)
# plt.savefig('None_vs_nearest-png.png')
# txt.set_text('Saved as a PDF')
# plt.savefig('None_vs_nearest-pdf.pdf')

# Here, however, we need to display the PDF on a webpage, which means
# the PDF must be converted into an image. For the purposes of this
# example, the 'Nearest_vs_none-pdf.pdf' has been pre-converted into
# 'Nearest_vs_none-pdf.png' at 80 dpi. We simply need to load and
# display it.
# The conversion is done with:
# gs -dNOPAUSE -dBATCH -dINTERPOLATE -sDEVICE=pngalpha \\
# -sOutputFile=Nearest_vs_none-png.pdf -r80 None_vs_nearest-pdf.pdf
pdf_im_path = cbook.get_sample_data('None_vs_nearest-pdf.png')
pdf_im = plt.imread(pdf_im_path)
fig2 = plt.figure(figsize=[8.0, 7.5])

Shows how to combine Normalization and Colormap instances to draw "levels" in pcolor, pcolormesh and imshow type plots in a similar way to the levels keyword argument to contour/contourf.

```python
import matplotlib.pyplot as plt
from matplotlib.colors import BoundaryNorm
from matplotlib.ticker import MaxNLocator
import numpy as np

# make these smaller to increase the resolution
dx, dy = 0.05, 0.05

# generate 2 2d grids for the x & y bounds
y, x = np.mgrid[slice(1, 5 + dy, dy),
                slice(1, 5 + dx, dx)]

z = np.sin(x)**10 + np.cos(10 + y*x) * np.cos(x)
```

# x and y are bounds, so z should be the value *inside* those bounds.
# Therefore, remove the last value from the z array.
z = z[:-1, :-1]
levels = MaxNLocator(nbins=15).tick_values(z.min(), z.max())

# pick the desired colormap, sensible levels, and define a normalization
# instance which takes data values and translates those into levels.
cmap = plt.get_cmap('PiYG')
norm = BoundaryNorm(levels, ncolors=cmap.N, clip=True)

fig, (ax0, ax1) = plt.subplots(nrows=2)

im = ax0.pcolormesh(x, y, z, cmap=cmap, norm=norm)
fig.colorbar(im, ax=ax0)
ax0.set_title('pcolormesh with levels')

# contours are *point* based plots, so convert our bound into point
# centers
cf = ax1.contourf(x[:-1, :-1] + dx/2.,
                 y[:-1, :-1] + dy/2., z, levels=levels,
                 cmap=cmap)
fig.colorbar(cf, ax=ax1)
ax1.set_title('contourf with levels')

# adjust spacing between subplots so `ax1`'s title and `ax0`'s tick labels
# don't overlap
fig.tight_layout()

plt.show()
93.7 images_contours_and_fields example code: streamplot_demo_features.py
Demo of the 'streamplot' function.

A streamplot, or streamline plot, is used to display 2D vector fields. This example shows a few features of the stream plot function:

* Varying the color along a streamline.
* Varying the density of streamlines.
* Varying the line width along a stream line.

```python
import numpy as np
import matplotlib.pyplot as plt

Y, X = np.mgrid[-3:3:100j, -3:3:100j]
U = -1 - X**2 + Y
V = 1 + X - Y**2
speed = np.sqrt(U*U + V*V)

fig0, ax0 = plt.subplots()
strm = ax0.streamplot(X, Y, U, V, color=U, linewidth=2, cmap=plt.cm.autumn)
fig0.colorbar(strm.lines)

fig1, (ax1, ax2) = plt.subplots(ncols=2)
ax1.streamplot(X, Y, U, V, density=[0.5, 1])

lw = 5*speed / speed.max()

```

Chapter 93. images_contours_and_fields Examples
```python
ax2.streamplot(X, Y, U, V, density=0.6, color='k', linewidth=lw)
plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)

93.8 images_contours_and_fields example code: streamplot_demo_masking.py

```python
""
Demo of the streamplot function with masking.

This example shows how streamlines created by the streamplot function skips masked regions and NaN values.
""

```import numpy as np
import matplotlib.pyplot as plt
```

```python
w = 3
Y, X = np.mgrid[-w:w:100j, -w:w:100j]
U = -1 - X**2 + Y
V = 1 + X - Y**2
```
speed = np.sqrt(U**2 + V**2)

mask = np.zeros(U.shape, dtype=bool)
mask[40:60, 40:60] = True
U[:20, :20] = np.nan
U = np.ma.array(U, mask=mask)

fig, ax = plt.subplots()
ax.streamplot(X, Y, U, V, color='r')

ax.imshow(~mask, extent=(-w, w, -w, w), alpha=0.5, interpolation='nearest', cmap=plt.cm.gray)

plt.show()
A streamplot, or streamline plot, is used to display 2D vector fields. This example shows a few features of the stream plot function:

* Varying the color along a streamline.
* Varying the density of streamlines.
* Varying the line width along a stream line.

```python
import numpy as np
import matplotlib.pyplot as plt

X, Y = (np.linspace(-3, 3, 100),
       np.linspace(-3, 3, 100))

U, V = np.mgrid[-3:3:100j, 0:0:100j]

seed_points = np.array([[-2, 0, 1], [-2, 0, 1]])

fig0, ax0 = plt.subplots()
strm = ax0.streamplot(X, Y, U, V, color=U, linewidth=2,
                      cmap=plt.cm.autumn, start_points=seed_points.T)
fig0.colorbar(strm.lines)

ax0.plot(seed_points[0], seed_points[1], 'bo')

ax0.axis((-3, 3, -3, 3))

plt.show()
```

**94.1 lines_bars_and_markers example code: barh_demo.py**

```python
import matplotlib.pyplot as plt
plt.rcdefaults()
import numpy as np
import matplotlib.pyplot as plt
```

---

*Simple demo of a horizontal bar chart.*

```python
import matplotlib.pyplot as plt
plt.rcdefaults()
import numpy as np
import matplotlib.pyplot as plt
```
```python
plt.rcdefaults()
fig, ax = plt.subplots()

# Example data
people = ('Tom', 'Dick', 'Harry', 'Slim', 'Jim')
y_pos = np.arange(len(people))
performance = 3 + 10 * np.random.rand(len(people))
error = np.random.rand(len(people))

ax.barh(y_pos, performance, xerr=error, align='center',
        color='green', ecolor='black')
ax.set_yticks(y_pos)
ax.set_yticklabels(people)
ax.invert_yaxis()  # labels read top-to-bottom
ax.set_xlabel('Performance')
ax.set_title('How fast do you want to go today?')

plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
Simple demo of the fill function.

```python
import numpy as np
import matplotlib.pyplot as plt

x = np.linspace(0, 1, 500)
y = np.sin(4 * np.pi * x) * np.exp(-5 * x)

fig, ax = plt.subplots()
ax.fill(x, y, zorder=10)
ax.grid(True, zorder=5)
plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see `Search examples`)
Demo of the fill function with a few features.

In addition to the basic fill plot, this demo shows a few optional features:

* Multiple curves with a single command.
* Setting the fill color.
* Setting the opacity (alpha value).

```
import numpy as np
import matplotlib.pyplot as plt

x = np.linspace(0, 2 * np.pi, 500)
y1 = np.sin(x)
y2 = np.sin(3 * x)

fig, ax = plt.subplots()
ax.fill(x, y1, 'b', x, y2, 'r', alpha=0.3)
plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
Demo of a simple plot with a custom dashed line.

A Line object’s `set_dashes` method allows you to specify dashes with a series of on/off lengths (in points).

```python
import numpy as np
import matplotlib.pyplot as plt

x = np.linspace(0, 10, 500)
dashes = [10, 5, 100, 5]  # 10 points on, 5 off, 100 on, 5 off

fig, ax = plt.subplots()
line1, = ax.plot(x, np.sin(x), '--', linewidth=2,
                 label='Dashes set retroactively')
line1.set_dashes(dashes)

line2, = ax.plot(x, -1 * np.sin(x), dashes=[30, 5, 10, 5],
                 label='Dashes set proactively')

ax.legend(loc='lower right')
```
94.5 lines_bars_and_markers example code: line_styles_reference.py

```python
import matplotlib.pyplot as plt

```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)

96.19 mplot3d example code: subplot3d_demo.py
3D plots as subplots

Demonstrate including 3D plots as subplots.

```
import matplotlib.pyplot as plt
from mpl_toolkits.mplot3d.axes3d import Axes3D, get_test_data
from matplotlib import cm
import numpy as np

# set up a figure twice as wide as it is tall
fig = plt.figure(figsize=plt.figaspect(0.5))

# First subplot
# set up the axes for the first plot
ax = fig.add_subplot(1, 2, 1, projection='3d')

# plot a 3D surface like in the example mplot3d/surface3d_demo
X = np.arange(-5, 5, 0.25)
Y = np.arange(-5, 5, 0.25)
X, Y = np.meshgrid(X, Y)
R = np.sqrt(X**2 + Y**2)
Z = np.sin(R)
surf = ax.plot_surface(X, Y, Z, rstride=1, cstride=1, cmap=cm.coolwarm,
linewidth=0, antialiased=False)
ax.set_zlim(-1.01, 1.01)
fig.colorbar(surf, shrink=0.5, aspect=10)

# Second subplot
# set up the axes for the second plot
ax = fig.add_subplot(1, 2, 2, projection='3d')

# plot a 3D wireframe like in the example mplot3d/wire3d_demo
X, Y, Z = get_test_data(0.05)
ax.plot_wireframe(X, Y, Z, rstride=10, cstride=10)

plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
Demonstrates plotting a 3D surface colored with the coolwarm color map. The surface is made opaque by using antialiased=False.

Also demonstrates using the LinearLocator and custom formatting for the z axis tick labels.

```python
from mpl_toolkits.mplot3d import Axes3D
import matplotlib.pyplot as plt
from matplotlib import cm
from matplotlib.ticker import LinearLocator, FormatStrFormatter
import numpy as np

fig = plt.figure()
ax = fig.gca(projection='3d')
```
# Make data.
X = np.arange(-5, 5, 0.25)
Y = np.arange(-5, 5, 0.25)
X, Y = np.meshgrid(X, Y)
R = np.sqrt(X**2 + Y**2)
Z = np.sin(R)

# Plot the surface.
surf = ax.plot_surface(X, Y, Z, cmap=cm.coolwarm,
                       linewidth=0, antialiased=False)

# Customize the z axis.
ax.set_zlim(-1.01, 1.01)
ax.zaxis.set_major_locator(LinearLocator(10))
ax.zaxis.set_major_formatter(FormatStrFormatter('%.02f'))

# Add a color bar which maps values to colors.
fig.colorbar(surf, shrink=0.5, aspect=5)

plt.show()
```python
from mpl_toolkits.mplot3d import Axes3D
import matplotlib.pyplot as plt
import numpy as np

fig = plt.figure()
ax = fig.add_subplot(111, projection='3d')

# Make data
u = np.linspace(0, 2 * np.pi, 100)
v = np.linspace(0, np.pi, 100)
x = 10 * np.outer(np.cos(u), np.sin(v))
y = 10 * np.outer(np.sin(u), np.sin(v))
z = 10 * np.outer(np.ones(np.size(u)), np.cos(v))
```

Demonstrates a very basic plot of a 3D surface using a solid color.

```
# Plot the surface
ax.plot_surface(x, y, z, color='b')
plt.show()

Keywords: python, matplotlib, pylab, example, codex (see Search examples)

96.22 mplot3d example code: surface3d_demo3.py

```python
from mpl_toolkits.mplot3d import Axes3D
import matplotlib.pyplot as plt
from matplotlib import cm
from matplotlib.ticker import LinearLocator

 Demonstrates plotting a 3D surface colored in a checkerboard pattern.
```

```python
from mpl_toolkits.mplot3d import Axes3D
import matplotlib.pyplot as plt
from matplotlib import cm
from matplotlib.ticker import LinearLocator
```
```python
import numpy as np

fig = plt.figure()
ax = fig.gca(projection='3d')

# Make data.
X = np.arange(-5, 5, 0.25)
xlen = len(X)
Y = np.arange(-5, 5, 0.25)
ylen = len(Y)
X, Y = np.meshgrid(X, Y)
R = np.sqrt(X**2 + Y**2)
Z = np.sin(R)

# Create an empty array of strings with the same shape as the meshgrid, and
# populate it with two colors in a checkerboard pattern.
colortuple = ('y', 'b')
colors = np.empty(X.shape, dtype=str)
for y in range(ylen):
    for x in range(xlen):
        colors[x, y] = colortuple[(x + y) % len(colortuple)]

# Plot the surface with face colors taken from the array we made.
surf = ax.plot_surface(X, Y, Z, facecolors=colors, linewidth=0)

# Customize the z axis.
ax.set_zlim(-1, 1)
ax.w_zaxis.set_major_locator(LinearLocator(6))

plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
3D surface with polar coordinates

Demonstrates plotting a surface defined in polar coordinates. Uses the reversed version of the YLgBu color map. Also demonstrates writing axis labels with latex math mode.

Example contributed by Armin Moser.

```python
from mpl_toolkits.mplot3d import Axes3D
from matplotlib import pyplot as plt
import numpy as np

fig = plt.figure()
ax = fig.add_subplot(111, projection='3d')

# Create the mesh in polar coordinates and compute corresponding Z.
r = np.linspace(0, 1.25, 50)
```
p = np.linspace(0, 2*np.pi, 50)
R, P = np.meshgrid(r, p)
Z = ((R**2 - 1)**2)

# Express the mesh in the cartesian system.
X, Y = R*np.cos(P), R*np.sin(P)

# Plot the surface.
ax.plot_surface(X, Y, Z, cmap=plt.cm.YlGnBu_r)

# Tweak the limits and add latex math labels.
ax.set_zlim(0, 1)
ax.set_xlabel(r'$\phi_{\text{real}}$')
ax.set_ylabel(r'$\phi_{\text{im}}$')
ax.set_zlabel(r'$V(\phi)$')

plt.show()

Keywords: python, matplotlib, pylab, example, codex (see Search examples)

96.24 mplot3d example code: text3d_demo.py
Demonstrates the placement of text annotations on a 3D plot.

Functionality shown:
- Using the text function with three types of 'zdir' values: None, an axis name (ex. 'x'), or a direction tuple (ex. (1, 1, 0)).
- Using the text function with the color keyword.
- Using the text2D function to place text on a fixed position on the ax object.

```python
from mpl_toolkits.mplot3d import Axes3D
import matplotlib.pyplot as plt

fig = plt.figure()
ax = fig.gca(projection='3d')

# Demo 1: zdir
zdirs = (None, 'x’, 'y’, 'z’, (1, 1, 0), (1, 1, 1))
xs = (1, 4, 4, 9, 4, 1)
ys = (2, 5, 8, 10, 1, 2)
zs = (10, 3, 8, 9, 1, 8)

for zdir, x, y, z in zip(zdirs, xs, ys, zs):
    label = '(%d, %d, %d), dir=%s' % (x, y, z, zdir)
    ax.text(x, y, z, label, zdir)

# Demo 2: color
ax.text(9, 0, 0, "red", color='red')

# Demo 3: text2D
# Placement 0, 0 would be the bottom left, 1, 1 would be the top right.
ax.text2D(0.05, 0.95, "2D Text", transform=ax.transAxes)

# Tweaking display region and labels
ax.set_xlim(0, 10)
ax.set_ylim(0, 10)
ax.set_zlim(0, 10)
ax.set_xlabel('X axis')
ax.set_ylabel('Y axis')
ax.set_zlabel('Z axis')

plt.show()
```

ax = fig.gca(projection='3d')
ax.tricontourf(triang, z, cmap=plt.cm.CMRmap)

# Customize the view angle so it's easier to understand the plot.
ax.view_init(elev=45.)

plt.show()

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
Triangular 3D surfaces

Plot a 3D surface with a triangular mesh.

from mpl_toolkits.mplot3d import Axes3D
import matplotlib.pyplot as plt
import numpy as np

n_radii = 8
n_angles = 36

# Make radii and angles spaces (radius r=0 omitted to eliminate duplication).
radii = np.linspace(0.125, 1.0, n_radii)
angles = np.linspace(0, 2*np.pi, n_angles, endpoint=False)

# Repeat all angles for each radius.
angles = np.repeat(angles[..., np.newaxis], n_radii, axis=1)

# Adapt number of angles if necessary to have the same number of points along
# all radii.
radians = np.linspace(0, 2*np.pi, 36, endpoint=False)

rads = np.empty((n_radii, n_angles+1))
rads[:, 1:-1] = radians
rads[:, -1] = radians[:, 0]

# Calculate corresponding z values (using a cosine function)
z = np.sin(rads**2)

# Adapt number of radii if necessary to have the same number of points along
# all angles.
rads = np.empty((n_radii+1, n_angles))
rads[1:, :] = radii[1:]
rads[0] = radii

# Calculate corresponding z values (using a cosine function)
z = np.sin(rads)**2

ax = plt.subplot(projection='3d')
anx = ax.plot_trisurf(rads, angles, z, 
                     # Shading parameters
                     cmap='viridis', 
                     lw=0.2, 
                     antialiased=True)

ax.set(xlim=(0, 1), ylim=(0, 1), zlim=(0, 1), 
       xlabel='X Label', ylabel='Y Label', zlabel='Z Label')

plt.show()
# Convert polar (radii, angles) coords to cartesian (x, y) coords.
# (0, 0) is manually added at this stage, so there will be no duplicate
# points in the (x, y) plane.
x = np.append(0, (radii*np.cos(angles)).flatten())
y = np.append(0, (radii*np.sin(angles)).flatten())

# Compute z to make the pringle surface.
z = np.sin(-x*y)

fig = plt.figure()
ax = fig.gca(projection=
3d
)

ax.plot_trisurf(x, y, z, linewidth=0.2, antialiased=True)

plt.show()

96.28 mplot3d example code: trisurf3d_demo2.py

---

More triangular 3D surfaces

Two additional examples of plotting surfaces with triangular mesh.

The first demonstrates use of plot_trisurf's triangles argument, and the
second sets a Triangulation object's mask and passes the object directly
```python
import numpy as np
import matplotlib.pyplot as plt
from mpl_toolkits.mplot3d import Axes3D
import matplotlib.tri as mtri

fig = plt.figure(figsize=plt.figaspect(0.5))

# First plot
u = np.linspace(0, 2.0 * np.pi, endpoint=True, num=50)
v = np.linspace(-0.5, 0.5, endpoint=True, num=10)
u, v = np.meshgrid(u, v)
u, v = u.flatten(), v.flatten()
x = (1 + 0.5 * v * np.cos(u / 2.0)) * np.cos(u)
y = (1 + 0.5 * v * np.cos(u / 2.0)) * np.sin(u)
z = 0.5 * v * np.sin(u / 2.0)
tri = mtri.Triangulation(u, v)
ax = fig.add_subplot(1, 2, 1, projection='3d')
ax.plot_trisurf(x, y, z, triangles=tri.triangles, cmap=plt.cm.Spectral)
ax.set_zlim(-1, 1)

# Second plot
n_angles = 36
n_radii = 8
min_radius = 0.25
radii = np.linspace(min_radius, 0.95, n_radii)
angles = np.linspace(0, 2*np.pi, n_angles, endpoint=False)
angles = np.repeat(angles[..., np.newaxis], n_radii, axis=1)
angles[:, 1::2] += np.pi/n_angles

x = (radii*np.cos(angles)).flatten()
```

---

96.28. mplot3d example code: trisurf3d_demo2.py

2289
```python
y = (radii*np.sin(angles)).flatten()
z = (np.cos(radii)*np.cos(angles*3.0)).flatten()

# Create the Triangulation; no triangles so Delaunay triangulation created.
triang = mtri.Triangulation(x, y)

# Mask off unwanted triangles.
xmid = x[triang.triangles].mean(axis=1)
ymid = y[triang.triangles].mean(axis=1)
mask = np.where(xmid**2 + ymid**2 < min_radius**2, 1, 0)
triang.set_mask(mask)

# Plot the surface.
ax = fig.add_subplot(1, 2, 2, projection='3d')
ax.plot_trisurf(triang, z, cmap=plt.cm.CMRmap)

plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)

**96.29 mplot3d example code: wire3d_animation_demo.py**
A very simple 'animation' of a 3D plot. See also rotate_axes3d_demo.

from __future__ import print_function

from mpl_toolkits.mplot3d import axes3d
import matplotlib.pyplot as plt
import numpy as np
import time

def generate(X, Y, phi):
    '''
    Generates Z data for the points in the X, Y meshgrid and parameter phi.
    '''
    R = 1 - np.sqrt(X**2 + Y**2)
    return np.cos(2 * np.pi * X + phi) * R

fig = plt.figure()
ax = fig.add_subplot(111, projection='3d')

# Make the X, Y meshgrid.
xs = np.linspace(-1, 1, 50)
y = np.linspace(-1, 1, 50)
X, Y = np.meshgrid(xs, ys)

# Set the z axis limits so they aren't recalculated each frame.
ax.set_zlim(-1, 1)

# Begin plotting.
wframe = None
tstart = time.time()
for phi in np.linspace(0, 180. / np.pi, 100):
    # If a line collection is already remove it before drawing.
    if wframe:
        ax.collections.remove(wframe)

    # Plot the new wireframe and pause briefly before continuing.
    Z = generate(X, Y, phi)
    wframe = ax.plot_wireframe(X, Y, Z, rstride=2, cstride=2)
    plt.pause(.001)

print('Average FPS: %f' % (100 / (time.time() - tstart)))

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
A very basic demonstration of a wireframe plot.

```python
from mpl_toolkits.mplot3d import axes3d
import matplotlib.pyplot as plt

fig = plt.figure()
ax = fig.add_subplot(111, projection='3d')

# Grab some test data.
X, Y, Z = axes3d.get_test_data(0.05)

# Plot a basic wireframe.
ax.plot_wireframe(X, Y, Z, rstride=10, cstride=10)

plt.show()
```
Keywords: python, matplotlib, pylab, example, codex (see Search examples)
96.31 mplot3d example code: wire3d_zero_stride.py

Column (x) stride set to 0

Row (y) stride set to 0
Matplotlib, Release 2.0.0

3D wireframe plots in one direction

Demonstrates that setting rstride or cstride to 0 causes wires to not be generated in the corresponding direction.

```
from mpl_toolkits.mplot3d import axes3d
import matplotlib.pyplot as plt

fig, [ax1, ax2] = plt.subplots(2, 1, figsize=(8, 12), subplot_kw={'projection': '3d'})

# Get the test data
X, Y, Z = axes3d.get_test_data(0.05)

# Give the first plot only wireframes of the type y = c
ax1.plot_wireframe(X, Y, Z, rstride=10, cstride=0)
ax1.set_title("Column (x) stride set to 0")

# Give the second plot only wireframes of the type x = c
ax2.plot_wireframe(X, Y, Z, rstride=0, cstride=10)
ax2.set_title("Row (y) stride set to 0")

plt.tight_layout()
plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
97.1 pie_and_polar_charts example code: pie_demo_features.py

Demo of a basic pie chart plus a few additional features.

In addition to the basic pie chart, this demo shows a few optional features:

* slice labels
* auto-labeling the percentage
* offsetting a slice with "explode"
* drop-shadow
* custom start angle

Note about the custom start angle:

The default ``startangle`` is 0, which would start the "Frogs" slice on the positive x-axis. This example sets ``startangle = 90`` such that everything is rotated counter-clockwise by 90 degrees, and the frog slice starts on the positive y-axis.

````
import matplotlib.pyplot as plt

# Pie chart, where the slices will be ordered and plotted counter-clockwise:
labels = 'Frogs', 'Hogs', 'Dogs', 'Logs'
sizes = [15, 30, 45, 10]
explode = (0, 0.1, 0, 0)  # only "explode" the 2nd slice (i.e. 'Hogs')

fig1, ax1 = plt.subplots()
ax1.pie(sizes, explode=explode, labels=labels, autopct='%.1f%%',
        shadow=True, startangle=90)
ax1.axis('equal')  # Equal aspect ratio ensures that pie is drawn as a circle.

plt.show()
````

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
Demo of bar plot on a polar axis.

```python
import numpy as np
import matplotlib.pyplot as plt

N = 20
theta = np.linspace(0.0, 2 * np.pi, N, endpoint=False)
radii = 10 * np.random.rand(N)
width = np.pi / 4 * np.random.rand(N)

ax = plt.subplot(111, projection='polar')
bars = ax.bar(theta, radii, width=width, bottom=0.0)

# Use custom colors and opacity
for r, bar in zip(radii, bars):
    bar.set_facecolor(plt.cm.viridis(r / 10.))
    bar.set_alpha(0.5)

plt.show()
```
Demo of scatter plot on a polar axis.

Size increases radially in this example and color increases with angle (just to verify the symbols are being scattered correctly).

```python
import numpy as np
import matplotlib.pyplot as plt

N = 150
r = 2 * np.random.rand(N)
theta = 2 * np.pi * np.random.rand(N)
area = 200 * r**2
colors = theta

ax = plt.subplot(111, projection='polar')
c = ax.scatter(theta, r, c=colors, s=area, cmap=plt.cm.hsv)
c.set_alpha(0.75)
```
plt.show()

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
matplotlib supports accented characters via TeX mathtext. The following accents are provided: \hat, \breve, \grave, \bar, \acute, \tilde, \vec, \dot, \ddot. All of them have the same syntax, e.g., to make an overbar you do \bar{o} or to make an o umlaut you do \ddot{o}. The shortcuts are also provided, e.g.,: "o \e \e \~n \.x \^y
```python
import matplotlib.pyplot as plt
plt.axes([0.1, 0.15, 0.8, 0.75])
plt.plot(range(10))
plt.title(r'\ddot{o}\acute{e}\grave{e}\hat{O}\breve{i}\bar{A}\tilde{n}\vec{q}\$'),
# shorthand is also supported and curly's are optional
plt.xlabel(r'''$"o\ddot o \ 'e\-n\.x\^y"$''', fontsize=20)
plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)

## 98.2 `pylab_examples` example code: agg_buffer.py

Use backend agg to access the figure canvas as an RGB string and then convert it to an array and pass it to Pillow for rendering.
import numpy as np

import matplotlib.pyplot as plt
from matplotlib.backends.backend_agg import FigureCanvasAgg

try:
    from PIL import Image
except ImportError:
    raise SystemExit("Pillow must be installed to run this example")

plt.plot([1, 2, 3])

canvas = plt.get_current_fig_manager().canvas
agg = canvas.switch_backends(FigureCanvasAgg)
agg.draw()
s = agg.tostring_rgb()

# get the width and the height to resize the matrix
l, b, w, h = agg.figure.bbox.bounds
w, h = int(w), int(h)

X = np.fromstring(s, np.uint8)
X.shape = h, w, 3

try:
    im = Image.fromstring("RGB", (w, h), s)
except Exception:
    im = Image.frombytes("RGB", (w, h), s)

# Uncomment this line to display the image using ImageMagick's
# 'display' tool.
# im.show()
98.3 `pylab_examples` example code: `agg_buffer_to_array.py`
import matplotlib.pyplot as plt
import numpy as np

# make an agg figure
fig, ax = plt.subplots()
ax.plot([1, 2, 3])
ax.set_title('a simple figure')
fig.canvas.draw()

# grab the pixel buffer and dump it into a numpy array
X = np.array(fig.canvas.renderer._renderer)

# now display the array X as an Axes in a new figure
fig2 = plt.figure()
ax2 = fig2.add_subplot(111, frameon=False)
ax2.imshow(X)
plt.show()

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
You can precisely layout text in data or axes (0,1) coordinates. This example shows you some of the alignment and rotation specifications to layout text.

```python
import matplotlib.pyplot as plt
from matplotlib.lines import Line2D
from matplotlib.patches import Rectangle

# build a rectangle in axes coords
left, width = .25, .5
bottom, height = .25, .5
right = left + width
top = bottom + height
ax = plt.gca()
p = plt.Rectangle((left, bottom), width, height,
                  fill=False,
                  )
p.set_transform(ax.transAxes)
p.set_clip_on(False)
ax.add_patch(p)
```
```python
ax.text(left, bottom, 'left top',
        horizontalalignment='left',
        verticalalignment='top',
        transform=ax.transAxes)

ax.text(left, bottom, 'left bottom',
        horizontalalignment='left',
        verticalalignment='bottom',
        transform=ax.transAxes)

ax.text(right, top, 'right bottom',
        horizontalalignment='right',
        verticalalignment='bottom',
        transform=ax.transAxes)

ax.text(right, top, 'right top',
        horizontalalignment='right',
        verticalalignment='top',
        transform=ax.transAxes)

ax.text(right, bottom, 'center top',
        horizontalalignment='center',
        verticalalignment='top',
        transform=ax.transAxes)

ax.text(left, 0.5*(bottom + top), 'right center',
        horizontalalignment='right',
        verticalalignment='center',
        rotation='vertical',
        transform=ax.transAxes)

ax.text(left, 0.5*(bottom + top), 'left center',
        horizontalalignment='left',
        verticalalignment='center',
        rotation='vertical',
        transform=ax.transAxes)

ax.text(0.5*(left + right), 0.5*(bottom + top), 'middle',
        horizontalalignment='center',
        verticalalignment='center',
        transform=ax.transAxes)

ax.text(right, 0.5*(bottom + top), 'centered',
        horizontalalignment='center',
        verticalalignment='center',
        rotation='vertical',
        transform=ax.transAxes)

ax.text(left, top, 'rotated
with newlines',
        horizontalalignment='center',
        verticalalignment='center',
```

98.4. `pylab_examples` example code: `alignment_test.py`
rotation=45,
transform=ax.transAxes)

plt.axis('off')
plt.show()

    plt.draw()
    plt.show()
Pyplot animation example.

The method shown here is only for very simple, low-performance use. For more demanding applications, look at the animation module and the examples that use it.

```python
import matplotlib.pyplot as plt
import numpy as np

x = np.arange(6)
y = np.arange(5)
z = x * y[:, np.newaxis]

for i in range(5):
    if i == 0:
        p = plt.imshow(z)
        fig = plt.gcf()
        plt.clim()  # clamp the color limits
        plt.title("Boring slide show")
    else:
```

Boring slide show
```python
z = z + 2
p.set_data(z)

print("step", i)
plt.pause(0.5)
```

### 98.7 `pylab_examples` example code: annotation_demo.py

**figure fraction**
a polar annotation
Some examples of how to annotate points in figures. You specify an annotation point \( xy=(x,y) \) and a text point \( xytext=(x,y) \) for the annotated points and text location, respectively. Optionally, you can specify the coordinate system of \( xy \) and \( xytext \) with one of the following strings for \( xycoords \) and \( textcoords \) (default is 'data')

- 'figure points' : points from the lower left corner of the figure
- 'figure pixels' : pixels from the lower left corner of the figure
- 'figure fraction' : 0,0 is lower left of figure and 1,1 is upper, right
- 'axes points' : points from lower left corner of axes
- 'axes pixels' : pixels from lower left corner of axes
- 'axes fraction' : 0,0 is lower left of axes and 1,1 is upper right
- 'offset points' : Specify an offset (in points) from the \( xy \) value
- 'offset pixels' : Specify an offset (in pixels) from the \( xy \) value
- 'data' : use the axes data coordinate system

Optionally, you can specify arrow properties which draws and arrow from the text to the annotated point by giving a dictionary of arrow properties

Valid keys are

- width : the width of the arrow in points
- frac : the fraction of the arrow length occupied by the head
The width of the base of the arrowhead in points
move the tip and base some percent away from the annotated point and text
any key for matplotlib.patches.polygon (e.g., facecolor)

For physical coordinate systems (points or pixels) the origin is the
(bottom, left) of the figure or axes.

```
import matplotlib.pyplot as plt
from matplotlib.patches import Ellipse
import numpy as np

# If only one location is given, the text and xypoint being
# annotated are assumed to be the same
fig = plt.figure()
ax = fig.add_subplot(111, autoscale_on=False, xlim=(-1, 5), ylim=(-3, 5))
t = np.arange(0.0, 5.0, 0.01)
s = np.cos(2*np.pi*t)
line, = ax.plot(t, s)
ax.annotate('figure pixels',
            xy=(10, 10), xycoords='figure pixels')

ax.annotate('figure points',
            xy=(80, 80), xycoords='figure points')

ax.annotate('point offset from data',
            xy=(2, 1), xycoords='data',
            xytext=(-15, 25), textcoords='offset points',
            arrowprops=dict(facecolor='black', shrink=0.05),
            horizontalalignment='right', verticalalignment='bottom')

ax.annotate('axes fraction',
            xy=(3, 1), xycoords='data',
            xytext=(0.8, 0.95), textcoords='axes fraction',
            arrowprops=dict(facecolor='black', shrink=0.05),
            horizontalalignment='right', verticalalignment='top')

ax.annotate('figure fraction',
            xy=(.025, .975), xycoords='figure fraction',
            horizontalalignment='left', verticalalignment='top',
            fontsize=20)

# use negative points or pixels to specify from right, top -10, 10
# is 10 points to the left of the right side of the axes and 10
# points above the bottom
ax.annotate('pixel offset from axes fraction',
            xy=(1, 0), xycoords='axes fraction',
            xytext=(-20, 20), textcoords='offset pixels')
```
# You can specify the xypoint and the xytext in different positions and
# coordinate systems, and optionally turn on a connecting line and mark
# the point with a marker. Annotations work on polar axes too.
# In the example below, the xy point is in native coordinates (xycoords
# defaults to 'data'). For a polar axes, this is in (theta, radius) space.
# The text in the example is placed in the fractional figure coordinate system.
# Text keyword args like horizontal and vertical alignment are respected.
fig = plt.figure()
ax = fig.add_subplot(111, projection='polar')
r = np.arange(0, 1, 0.001)
theta = 2*2*np.pi*r
line, = ax.plot(theta, r)

ind = 800
thisr, thistheta = r[ind], theta[ind]
ax.plot([thistheta], [thisr], 'o')
ax.annotate('a polar annotation',
            xy=(thistheta, thisr),  # theta, radius
            xytext=(0.05, 0.05),  # fraction, fraction
            textcoords='figure fraction',
            arrowprops=dict(facecolor='black', shrink=0.05),
            horizontalalignment='left',
            verticalalignment='bottom')

# You can also use polar notation on a cartesian axes. Here the native
# coordinate system ('data') is cartesian, so you need to specify the
# xycoords and textcoords as 'polar' if you want to use (theta, radius).
el = Ellipse((0, 0), 10, 20, facecolor='r', alpha=0.5)

fig = plt.figure()
ax = fig.add_subplot(111, aspect='equal')
ax.add_artist(el)
el.set_clip_box(ax.bbox)
ax.annotate('the top',
            xy=(np.pi/2., 10.),  # theta, radius
            xytext=(np.pi/3, 20.),  # theta, radius
            xycoords='polar',
            textcoords='polar',
            arrowprops=dict(facecolor='black', shrink=0.05),
            horizontalalignment='left',
            verticalalignment='bottom',
            clip_on=True)  # clip to the axes bounding box

ax.set_xlim([-20, 20])
ax.set_ylim([-20, 20])

Thanks Josh Hemann for the example

This examples comes from an application in which grade school gym teachers wanted to be able to show parents how their child did across a handful of fitness tests, and importantly, relative to how other children did. To extract the plotting code for demo purposes, we'll just make up some data for little Johnny Doe...

```python
import numpy as np
import matplotlib.pyplot as plt
from matplotlib.ticker import MaxNLocator
from collections import namedtuple

Student = namedtuple('Student', ['name', 'grade', 'gender'])
Score = namedtuple('Score', ['score', 'percentile'])

Cohort Size: 62
0 10 20 30 40 50 60 70 80 90 100
Johnny Doe
Push Ups
16th
Agility
2nd
Mile Run
54th
Flexed Arm
Hang
Pacer Test
27th
Test Scores
14
17 sec
12:52
min:sec
4.8 sec
7 laps

# GLOBAL CONSTANTS
testNames = ['Pacer Test', 'Flexed Arm\n Hang', 'Mile Run', 'Agility', 'Push Ups']
testMeta = dict(zip(testNames, ['laps', 'sec', 'min:sec', 'sec', '']))

def attach_ordinal(num):
    """helper function to add ordinal string to integers
    1 -> 1st
    56 -> 56th
    """
    suffixes = dict((str(i), v) for i, v in enumerate(['th', 'st', 'nd', 'rd', 'th', 'th', 'th', 'th']))
    v = str(num)
    # special case early teens
    if v in {'11', '12', '13'}:
        return v + 'th'
    return v + suffixes[v[-1]]

def format_score(scr, test):
    """Build up the score labels for the right Y-axis by first appending a carriage return to each string and then tacking on the appropriate meta information (i.e., 'laps' vs 'seconds'). We want the labels centered on the ticks, so if there is no meta info (like for pushups) then don't add the carriage return to the string
    """

Broken axis example, where the y-axis will have a portion cut out.

```python
import matplotlib.pyplot as plt
import numpy as np

# 30 points between [0, 0.2) originally made using np.random.rand(30)*.2
pts = np.array([0.015, 0.166, 0.133, 0.159, 0.041, 0.024, 0.195, 0.039, 0.161, 0.018,
                0.143, 0.056, 0.125, 0.096, 0.094, 0.051, 0.043, 0.021, 0.138, 0.075,
                0.109, 0.195, 0.050, 0.074, 0.079, 0.155, 0.020, 0.010, 0.061, 0.008])

# Now let's make two outlier points which are far away from everything.
pts[[3, 14]] += .8

# If we were to simply plot pts, we'd lose most of the interesting
details due to the outliers. So let's 'break' or 'cut-out' the y-axis
# into two portions - use the top (ax) for the outliers, and the bottom
# (ax2) for the details of the majority of our data
f, (ax, ax2) = plt.subplots(2, 1, sharex=True)
```
# plot the same data on both axes
ax.plot(pts)
ax2.plot(pts)

# zoom-in / limit the view to different portions of the data
ax.set_ylim(.78, 1.)  # outliers only
ax2.set_ylim(0, .22)  # most of the data

# hide the spines between ax and ax2
ax.spines['bottom'].set_visible(False)
ax2.spines['top'].set_visible(False)
ax.xaxis.tick_top()
ax.tick_params(labeltop='off')  # don't put tick labels at the top
ax2.xaxis.tick_bottom()

# This looks pretty good, and was fairly painless, but you can get that
# cut-out diagonal lines look with just a bit more work. The important
# thing to know here is that in axes coordinates, which are always
# between 0-1, spine endpoints are at these locations (0,0), (0,1),
# (1,0), and (1,1). Thus, we just need to put the diagonals in the
# appropriate corners of each of our axes, and so long as we use the
# right transform and disable clipping.

d = .015  # how big to make the diagonal lines in axes coordinates
# arguments to pass to plot, just so we don't keep repeating them
kwargs = dict(transform=ax.transAxes, color='k', clip_on=False)
ax.plot((-d, +d), (-d, +d), **kwargs)  # top-left diagonal
ax.plot((1 - d, 1 + d), (-d, +d), **kwargs)  # top-right diagonal
kwargs.update(transform=ax2.transAxes)  # switch to the bottom axes
ax2.plot((-d, +d), (1 - d, 1 + d), **kwargs)  # bottom-left diagonal
ax2.plot((1 - d, 1 + d), (1 - d, 1 + d), **kwargs)  # bottom-right diagonal

# What's cool about this is that now if we vary the distance between
# ax and ax2 via f.subplots_adjust(hspace=...) or plt.subplot_tool(),
# the diagonal lines will move accordingly, and stay right at the tips
# of the spines they are 'breaking'

plt.show()

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
Make a "broken" horizontal bar plot, i.e., one with gaps

```
import matplotlib.pyplot as plt

fig, ax = plt.subplots()
ax.broken_barh([(110, 30), (150, 10)], (10, 9), facecolors='blue')
ax.broken_barh([(10, 50), (100, 20), (130, 10)], (20, 9),
               facecolors=('red', 'yellow', 'green'))
ax.set_ylim(5, 35)
ax.set_xlim(0, 200)
ax.set_xlabel('seconds since start')
ax.set_yticks([15, 25])
ax.set_yticklabels(['Bill', 'Jim'])
ax.grid(True)
ax.annotate('race interrupted', (61, 25),
            xytext=(0.8, 0.9), textcoords='axes fraction',
            arrowprops=dict(facecolor='black', shrink=0.05),
            fontsize=16,
            horizontalalignment='right', verticalalignment='top')

plt.show()
```
# sometimes it is nice to have ticklabels centered. mpl currently
# associates a label with a tick, and the label can be aligned
# 'center', 'left', or 'right' using the horizontal alignment property:
#
# for label in ax.xaxis.get_xticklabels():
#     label.set_horizontalalignment('right')
#
# but this doesn't help center the label between ticks. One solution
# is to "face it". Use the minor ticks to place a tick centered
# between the major ticks. Here is an example that labels the months,
# centered between the ticks

import numpy as np
import matplotlib.cbook as cbook
import matplotlib.dates as dates
import matplotlib.ticker as ticker
import matplotlib.pyplot as plt
# load some financial data; apple's stock price
fh = cbook.get_sample_data('aapl.npy.gz')

try:
    # Python3 cannot load python2 .npy files with datetime(object) arrays
    # unless the encoding is set to bytes. However this option was
    # not added until numpy 1.10 so this example will only work with
    # python 2 or with numpy 1.10 and later.
    r = np.load(fh, encoding='bytes')
except TypeError:
    r = np.load(fh)
fh.close()

r = r[-250:]  # get the last 250 days

fig, ax = plt.subplots()
ax.plot(r.date, r.adj_close)
ax.xaxis.set_major_locator(dates.MonthLocator())
ax.xaxis.set_minor_locator(dates.MonthLocator(bymonthday=15))
ax.xaxis.set_major_formatter(ticker.NullFormatter())
ax.xaxis.set_minor_formatter(dates.DateFormatter('%b'))

for tick in ax.xaxis.get_minor_ticks():
    tick.tick1line.set_markersize(0)
    tick.tick2line.set_markersize(0)
    tick.label1.set_horizontalalignment('center')

imid = len(r)//2
ax.set_xlabel(str(r.date[imid].year))
plt.show()
Compute the coherence of two signals

```python
import numpy as np
import matplotlib.pyplot as plt

# make a little extra space between the subplots
plt.subplots_adjust(wspace=0.5)

dt = 0.01
t = np.arange(0, 30, dt)
nse1 = np.random.randn(len(t))  # white noise 1
nse2 = np.random.randn(len(t))  # white noise 2
r = np.exp(-t/0.05)

# two signals with a coherent part and a random part
s1 = 0.01*np.sin(2*np.pi*10*t) + cnse1
s2 = 0.01*np.sin(2*np.pi*10*t) + cnse2
```
```python
plt.subplot(211)
plt.plot(t, s1, t, s2)
plt.xlim(0, 5)
plt.xlabel('time')
plt.ylabel('s1 and s2')
plt.grid(True)

plt.subplot(212)
cxy, f = plt.cohere(s1, s2, 256, 1./dt)
plt.ylabel('coherence')
plt.show()
```

```python
matplotlib gives you 5 ways to specify colors,

1) as a single letter string, ala MATLAB

2) as an html style hex string or html color name
```
3) as an R,G,B tuple, where R,G,B, range from 0-1

4) as a string representing a floating point number from 0 to 1, corresponding to shades of gray.

5) as a special color "Cn", where n is a number 0-9 specifying the nth color in the currently active color cycle.

See help(colors) for more info.

```
import matplotlib.pyplot as plt
import numpy as np

plt.subplot(111, facecolor='darkslategray')
t = np.arange(0.0, 2.0, 0.01)
s = np.sin(2*np.pi*t)
plt.plot(t, s, 'C1')
plt.xlabel('time (s)', color='C1')
plt.ylabel('voltage (mV)', color='0.5') # grayscale color
plt.title('About as silly as it gets, folks', color='#afeeee')
plt.show()
```

# This makes the original colorbar look a bit out of place,
# so let's improve its position.

l, b, w, h = plt.gca().get_position().bounds
ll, bb, ww, hh = CB.ax.get_position().bounds
CB.ax.set_position([ll, b + 0.1*h, ww, h*0.8])

plt.show()
Test combinations of contouring, filled contouring, and image plotting. For contour labelling, see contour_demo.py.

The emphasis in this demo is on showing how to make contours register correctly on images, and on how to get both of them oriented as desired. In particular, note the usage of the "origin" and "extent" keyword arguments to imshow and contour.

```python
import matplotlib.pyplot as plt
import numpy as np
from matplotlib import mlab, cm

# Default delta is large because that makes it fast, and it illustrates
# the correct registration between image and contours.
delta = 0.5
extent = (-3, 4, -4, 3)

x = np.arange(-3.0, 4.001, delta)
y = np.arange(-4.0, 3.001, delta)
X, Y = np.meshgrid(x, y)
```
Z1 = mlab.bivariate_normal(X, Y, 1.0, 1.0, 0.0, 0.0)
Z2 = mlab.bivariate_normal(X, Y, 1.5, 0.5, 1, 1)
Z = (Z1 - Z2) * 10

levels = np.arange(-2.0, 1.601, 0.4)  # Boost the upper limit to avoid truncation errors.

norm = cm.colors.Normalize(vmax=abs(Z).max(), vmin=-abs(Z).max())
cmap = cm.PRGn

fig = plt.figure()
fig.subplots_adjust(hspace=0.3)

plt.subplot(2, 2, 1)
cset1 = plt.contourf(X, Y, Z, levels,
                     cmap=cm.get_cmap(cmap, len(levels) - 1),
                     norm=norm,
                     )
# It is not necessary, but for the colormap, we need only the
# number of levels minus 1. To avoid discretization error, use
# either this number or a large number such as the default (256).

# If we want lines as well as filled regions, we need to call
# contour separately; don't try to change the edgecolor or edgewidth
# of the polygons in the collections returned by contourf.
# Use levels output from previous call to guarantee they are the same.
cset2 = plt.contour(X, Y, Z, cset1.levels, colors='k')

# We don't really need dashed contour lines to indicate negative
# regions, so let's turn them off.
for c in cset2.collections:
    c.set_linestyle('solid')

# It is easier here to make a separate call to contour than
# to set up an array of colors and linewidths.
# We are making a thick green line as a zero contour.
# Specify the zero level as a tuple with only 0 in it.
cset3 = plt.contour(X, Y, Z, (0,), colors='g', linewidths=2)

pylab_examples example code: custom_cmap.py

![Custom Color Maps Example](image-url)
Custom Blue-Red colormaps

Varying alpha
Creating a colormap from a list of colors
-----------------------------------------
Creating a colormap from a list of colors can be done with the `from_list` method of `LinearSegmentedColormap`. You must pass a list of RGB tuples that define the mixture of colors from 0 to 1.

Creating custom colormaps
-------------------------
It is also possible to create a custom mapping for a colormap. This is accomplished by creating dictionary that specifies how the RGB channels change from one end of the cmap to the other.

Example: suppose you want red to increase from 0 to 1 over the bottom half, green to do the same over the middle half, and blue over the top half. Then you would use:

```python
cdict = {'red':  [(0.0, 0.0, 0.0),
                (0.5, 1.0, 1.0),
                (1.0, 1.0, 1.0))},

green': [(0.0, 0.0, 0.0),
          (0.25, 0.0, 0.0),
          (0.75, 1.0, 1.0),
          (1.0, 1.0, 1.0))},

'blue': [(0.0, 0.0, 0.0),
         (0.5, 0.0, 0.0),
         (1.0, 1.0, 1.0))}
```

If, as in this example, there are no discontinuities in the r, g, and b components, then it is quite simple: the second and third element of each tuple, above, is the same--call it "y". The first element ("x") defines interpolation intervals over the full range of 0 to 1, and it must span that whole range. In other words, the values of x divide the 0-to-1 range into a set of segments, and y gives the end-point color values for each segment.

Now consider the green. cdict['green'] is saying that for 
0 <= x <= 0.25, y is zero; no green.
0.25 < x <= 0.75, y varies linearly from 0 to 1.
x > 0.75, y remains at 1, full green.

If there are discontinuities, then it is a little more complicated. Label the 3 elements in each row in the cdict entry for a given color as (x, y0, y1). Then for values of x between x[i] and x[i+1] the color value is interpolated between y[i] and y[i+1].
Going back to the cookbook example, look at cdict['red']; because y0 != y1, it is saying that for x from 0 to 0.5, red increases from 0 to 1, but then it jumps down, so that for x from 0.5 to 1, red increases from 0.7 to 1. Green ramps from 0 to 1 as x goes from 0 to 0.5, then jumps back to 0, and ramps back to 1 as x goes from 0.5 to 1.

row i: x y0 y1
/    /    /
row i+1: x y0 y1

Above is an attempt to show that for x in the range x[i] to x[i+1], the interpolation is between y1[i] and y0[i+1]. So, y0[0] and y1[-1] are never used.

```python
# Make some illustrative fake data:

x = np.arange(0, np.pi, 0.1)
y = np.arange(0, 2*np.pi, 0.1)
X, Y = np.meshgrid(x, y)
Z = np.cos(X) * np.sin(Y) * 10

# --- Colormaps from a list ---

colors = [(1, 0, 0), (0, 1, 0), (0, 0, 1)]  # R -> G -> B
n_bins = [3, 6, 10, 100]  # Discretizes the interpolation into bins
cmap_name = 'my_list'
fig, axs = plt.subplots(2, 2, figsize=(6, 9))
fig.subplots_adjust(left=0.02, bottom=0.06, right=0.95, top=0.94, wspace=0.05)
for n_bin, ax in zip(n_bins, axs.ravel()):
    # Create the colormap
    cm = LinearSegmentedColormap.from_list(cmap_name, colors, N=n_bin)
    # Fewer bins will result in "coarser" colormap interpolation
    im = ax.imshow(Z, interpolation='nearest', origin='lower', cmap=cm)
    ax.set_title('N bins: %s' % n_bin)
    fig.colorbar(im, ax=ax)

# --- Custom colormaps ---

cdict1 = {'red': ((0.0, 0.0, 0.0),
                  (0.5, 0.0, 0.1),
                  (1.0, 1.0, 1.0)),

             'green': ((0.0, 0.0, 0.0),
                        (1.0, 0.0, 0.0)),

             'blue': ((0.0, 0.0, 1.0),
                      (0.5, 0.1, 0.0),
                      (1.0, 0.0, 0.0))}
cdict2 = {
    'red': ((0.0, 0.0, 0.0),
            (0.5, 0.0, 1.0),
            (1.0, 0.1, 1.0)),

    'green': ((0.0, 0.0, 0.0),
               (1.0, 0.0, 0.0)),

    'blue': ((0.0, 0.0, 0.1),
             (0.5, 1.0, 0.0),
             (1.0, 0.0, 0.0))
}

cdict3 = {
    'red': ((0.0, 0.0, 0.0),
             (0.25, 0.0, 0.0),
             (0.5, 0.8, 1.0),
             (0.75, 1.0, 1.0),
             (1.0, 0.4, 1.0)),

    'green': ((0.0, 0.0, 0.0),
               (0.25, 0.0, 0.0),
               (0.5, 0.9, 0.9),
               (0.75, 0.0, 0.0),
               (1.0, 0.0, 0.0)),

    'blue': ((0.0, 0.0, 0.4),
              (0.25, 1.0, 1.0),
              (0.5, 1.0, 0.8),
              (0.75, 0.0, 0.0),
              (1.0, 0.0, 0.0))
}

# Make a modified version of cdict3 with some transparency
# in the middle of the range.
cdict4 = cdict3.copy()
cdict4['alpha'] = ((0.0, 1.0, 1.0),
                   # (0.25,1.0, 1.0),
                   (0.5, 0.3, 0.3),
                   # (0.75,1.0, 1.0),
                   (1.0, 1.0, 1.0))

# Now we will use this example to illustrate 3 ways of
# handling custom colormaps.
# First, the most direct and explicit:
blue_red1 = LinearSegmentedColormap('BlueRed1', cdict1)

# Second, create the map explicitly and register it.
# Like the first method, this method works with any kind
# of Colormap, not just
# a LinearSegmentedColormap:
blue_red2 = LinearSegmentedColormap('BlueRed2', cdict2)
plt.register_cmap(cmap=blue_red2)

# Third, for LinearSegmentedColormap only,
# leave everything to register_cmap:

plt.register_cmap(name='BlueRed3', data=cdict3) # optional lut kwarg
plt.register_cmap(name='BlueRedAlpha', data=cdict4)

# Make the figure:
fig, axs = plt.subplots(2, 2, figsize=(6, 9))
fig.subplots_adjust(left=0.02, bottom=0.06, right=0.95, top=0.94, wspace=0.05)

# Make 4 subplots:
im1 = axs[0, 0].imshow(Z, interpolation='nearest', cmap=blue_red1)
fig.colorbar(im1, ax=axs[0, 0])
cmap = plt.get_cmap('BlueRed2')
im2 = axs[1, 0].imshow(Z, interpolation='nearest', cmap=cmap)
fig.colorbar(im2, ax=axs[1, 0])

# Now we will set the third cmap as the default. One would
# not normally do this in the middle of a script like this;
# it is done here just to illustrate the method.
plt.rcParams['image.cmap'] = 'BlueRed3'
im3 = axs[0, 1].imshow(Z, interpolation='nearest')
fig.colorbar(im3, ax=axs[0, 1])
axs[0, 1].set_title("Alpha = 1")

# Or as yet another variation, we can replace the rcParams
# specification "before" the imshow with the following "after"
# imshow.
# This sets the new default "and" sets the colormap of the last
# image-like item plotted via pyplot, if any.
#
# Draw a line with low zorder so it will be behind the image.
axs[1, 1].plot([0, 10*np.pi], [0, 20*np.pi], color='c', lw=20, zorder=-1)
im4 = axs[1, 1].imshow(Z, interpolation='nearest')
fig.colorbar(im4, ax=axs[1, 1])

# Here it is: changing the colormap for the current image and its
# colorbar after they have been plotted.
im4.set_cmap('BlueRedAlpha')
axs[1, 1].set_title("Varying alpha")
#
```python
fig.suptitle('Custom Blue-Red colormaps', fontsize=16)
plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)

### 98.47 pylab_examples example code: custom_figure_class.py

```python
my title

from matplotlib.pyplot import figure, show
from matplotlib.figure import Figure

class MyFigure(Figure):
    def __init__(self, *args, **kwargs):
        custom kwarg figtitle is a figure title
        figtitle = kwarg.pop('figtitle', 'hi mom')
```

You can pass a custom Figure constructor to figure if you want to derive from the default Figure. This simple example creates a figure with a figure title.
The new ticker code was designed to explicitly support user customized ticking. The documentation http://matplotlib.org/matplotlib.ticker.html details this process. That code defines a lot of preset tickers but was primarily designed to be user extensible.

In this example a user defined function is used to format the ticks in millions of dollars on the y axis.
```python
from matplotlib.ticker import FuncFormatter
import matplotlib.pyplot as plt
import numpy as np

x = np.arange(4)
money = [1.5e5, 2.5e6, 5.5e6, 2.0e7]

def millions(x, pos):
    'The two args are the value and tick position'
    return '$%.1fM' % (x*1e-6)

formatter = FuncFormatter(millions)

fig, ax = plt.subplots()
ax.yaxis.set_major_formatter(formatter)
plt.bar(x, money)
plt.xticks(x, ('Bill', 'Fred', 'Mary', 'Sue'))
plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
I'm not trying to make a good looking figure here, but just to show some examples of customizing rc params on the fly.

If you like to work interactively, and need to create different sets of defaults for figures (e.g., one set of defaults for publication, one set for interactive exploration), you may want to define some functions in a custom module that set the defaults, e.g.,

```python
def set_pub():
    rc('font', weight='bold')  # bold fonts are easier to see
    rc('tick', labelsize=15)  # tick labels bigger
    rc('lines', lw=1, color='k')  # thicker black lines (no budget for color!)
    rc('grid', c='.5', ls='-', lw=0.5)  # solid gray grid lines
    rc('savefig', dpi=300)  # higher res outputs
```

Then as you are working interactively, you just need to do

```python
>>> set_pub()
>>> subplot(111)
```
>>> plot([1,2,3])
>>> savefig('myfig')
>>> rcdefaults()  # restore the defaults

""
import matplotlib.pyplot as plt

plt.subplot(311)
plt.plot([1, 2, 3])

# the axes attributes need to be set before the call to subplot
plt.rc('font', weight='bold')
plt.rc('xtick.major', size=5, pad=7)
plt.rc('xtick', labelsize=15)

# using aliases for color, linestyle and linewidth; gray, solid, thick
plt.rc('grid', c='0.5', ls='-', lw=5)
plt.rc('lines', lw=2, color='g')

plt.subplot(312)
plt.plot([1, 2, 3])
plt.grid(True)

plt.rcdefaults()
plt.subplot(313)
plt.plot([1, 2, 3])
plt.plot([1, 2, 3])
plt.grid(True)
plt.show()

Keywords: python, matplotlib, pylab, example, codex (see Search examples)

98.51  *pylab_examples* example code: *date_demo_convert.py*

```python
import datetime
import matplotlib.pyplot as plt
```

98.51.  *pylab_examples* example code: *date_demo_convert.py*
from matplotlib.dates import DayLocator, HourLocator, DateFormatter, drange
from numpy import arange

date1 = datetime.datetime(2000, 3, 2)
date2 = datetime.datetime(2000, 3, 6)
delta = datetime.timedelta(hours=6)
dates = drange(date1, date2, delta)

y = arange(len(dates)*1.0)

fig, ax = plt.subplots()
ax.plot_date(dates, y*y)

# this is superfluous, since the autoscaler should get it right, but
# use date2num and num2date to convert between dates and floats if
# you want; both date2num and num2date convert an instance or sequence
ax.set_xlim(dates[0], dates[-1])

# The hour locator takes the hour or sequence of hours you want to
tick, not the base multiple
ax.xaxis.set_major_locator(DayLocator())
ax.xaxis.set_minor_locator(HourLocator(arange(0, 25, 6)))
ax.xaxis.set_major_formatter(DateFormatter('%Y-%m-%d'))
ax.fmt_xdata = DateFormatter('%Y-%m-%d %H:%M:%S')
fig.autofmt_xdate()

plt.show()
Show how to use an rrule instance to make a custom date ticker - here we put a tick mark on every 5th easter

See https://moin.conectiva.com.br/DateUtil for help with rrules

```python
import matplotlib.pyplot as plt
from matplotlib.dates import YEARLY, DateFormatter, rrulewrapper, RRuleLocator, drange
import numpy as np
import datetime

# tick every 5th easter
rule = rrulewrapper(YEARLY, byeaster=1, interval=5)
loc = RRuleLocator(rule)
formatter = DateFormatter('%m/%d/%y')
date1 = datetime.date(1952, 1, 1)
date2 = datetime.date(2004, 4, 12)
delta = datetime.timedelta(days=100)

dates = drange(date1, date2, delta)
s = np.random.rand(len(dates))  # make up some random y values
```
When plotting daily data, a frequent request is to plot the data ignoring skips, e.g., no extra spaces for weekends. This is particularly common in financial time series, when you may have data for M-F and not Sat, Sun and you don't want gaps in the x axis. The approach is to simply use the integer index for the xdata and a custom tick formatter to get the appropriate date string for a given index.
```python
from __future__ import print_function
import numpy as np
from matplotlib.mlab import csv2rec
import matplotlib.pyplot as plt
import matplotlib.cbook as cbook
from matplotlib.ticker import Formatter

datafile = cbook.get_sample_data('msft.csv', asfileobj=False)
print('loading %s' % datafile)
r = csv2rec(datafile)[40:]

class MyFormatter(Formatter):
    def __init__(self, dates, fmt='%Y-%m-%d'):
        self.dates = dates
        self.fmt = fmt

    def __call__(self, x, pos=0):
        'Return the label for time x at position pos'
        ind = int(np.round(x))
        if ind >= len(self.dates) or ind < 0:
            return ''

        return self.dates[ind].strftime(self.fmt)

formatter = MyFormatter(r.date)

fig, ax = plt.subplots()
ax.xaxis.set_major_formatter(formatter)
ax.plot(np.arange(len(r)), r.close, 'o-')
fig.autofmt_xdate()
plt.show()

hexbin is an axes method or pyplot function that is essentially
a pcolor of a 2-D histogram with hexagonal cells. It can be much more informative than a scatter plot; in the first subplot below, try substituting 'scatter' for 'hexbin'.

```python
import numpy as np
import matplotlib.pyplot as plt

np.random.seed(0)
n = 100000
x = np.random.standard_normal(n)
y = 2.0 + 3.0 * x + 4.0 * np.random.standard_normal(n)
xmin = x.min()
xmax = x.max()
ymin = y.min()
ymax = y.max()

fig, axs = plt.subplots(ncols=2, sharey=True, figsize=(7, 4))
fig.subplots_adjust(hspace=0.5, left=0.07, right=0.93)
ax = axs[0]
hb = ax.hexbin(x, y, gridsize=50, cmap='inferno')
ax.axis([xmin, xmax, ymin, ymax])
ax.set_title("Hexagon binning")
cb = fig.colorbar(hb, ax=ax)
cb.set_label('counts')

ax = axs[1]
hb = ax.hexbin(x, y, gridsize=50, bins='log', cmap='inferno')
ax.axis([xmin, xmax, ymin, ymax])
ax.set_title("With a log color scale")
cb = fig.colorbar(hb, ax=ax)
cb.set_label('log10(N)')
plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)

98.101 pylab_examples example code: image_interp.py
The same (small) array, interpolated with three different interpolation methods.

The center of the pixel at \( A[i,j] \) is plotted at \( i+0.5, i+0.5 \). If you are using interpolation='nearest', the region bounded by \( (i,j) \) and \( (i+1,j+1) \) will have the same color. If you are using interpolation, the pixel center will have the same color as it does with nearest, but other pixels will be interpolated between the neighboring pixels.

Earlier versions of matplotlib (<0.63) tried to hide the edge effects from you by setting the view limits so that they would not be visible. A recent bug fix in antigrain, and a new implementation in the matplotlib._image module which takes advantage of this fix, no longer makes this necessary. To prevent edge effects, when doing interpolation, the matplotlib._image module now pads the input array with identical pixels around the edge. e.g., if you have a 5x5 array with colors a-y as below

```
a b c d e
f g h i j
k l m n o
p q r s t
u v w x y
```
the `_image` module creates the padded array,

```
  a a b c d e e
  a a b c d e e
  f f g h i j j
  k k l m n o o
  p p q r s t t
  o u v w x y y
  o u v w x y y
```
does the interpolation/resizing, and then extracts the central region. This allows you to plot the full range of your array w/o edge effects, and for example to layer multiple images of different sizes over one another with different interpolation methods - see examples/layer_images.py. It also implies a performance hit, as this new temporary, padded array must be created. Sophisticated interpolation also implies a performance hit, so if you need maximal performance or have very large images, interpolation='nearest' is suggested.

```python
import matplotlib.pyplot as plt
import numpy as np
A = np.random.rand(5, 5)
plt.figure(1)
plt.imshow(A, interpolation='nearest')
plt.grid(True)
plt.figure(2)
plt.imshow(A, interpolation='bilinear')
plt.grid(True)
plt.figure(3)
plt.imshow(A, interpolation='bicubic')
plt.grid(True)
plt.show()
```

cbar = fig.colorbar(im, extend='both', spacing='proportional',
shrink=0.9, ax=ax2)
cbar.set_label('proportional')
```
This illustrates the NonUniformImage class. It is not available via an Axes method but it is easily added to an Axes instance as shown here.

```python
import numpy as np
import matplotlib.pyplot as plt
from matplotlib.image import NonUniformImage
from matplotlib import cm

interp = 'nearest'

# Linear x array for cell centers:
x = np.linspace(-4, 4, 9)
```
# Highly nonlinear x array:
x2 = x**3

y = np.linspace(-4, 4, 9)

z = np.sqrt(x[np.newaxis, :]**2 + y[:, np.newaxis]**2)

fig, axs = plt.subplots(nrows=2, ncols=2)
fig.subplots_adjust(bottom=0.07, hspace=0.3)
fig.suptitle('NonUniformImage class', fontsize='large')
ax = axs[0, 0]
im = NonUniformImage(ax, interpolation=interp, extent=(-4, 4, -4, 4), cmap=cm.Purples)
im.set_data(x, y, z)
ax.images.append(im)
ax.set_xlim(-4, 4)
ax.set_ylim(-4, 4)
ax.set_title(interp)

ax = axs[0, 1]
im = NonUniformImage(ax, interpolation=interp, extent=(-64, 64, -4, 4), cmap=cm.Purples)
im.set_data(x2, y, z)
ax.images.append(im)
ax.set_xlim(-64, 64)
ax.set_ylim(-4, 4)
ax.set_title(interp)

interp = 'bilinear'

ax = axs[1, 0]
im = NonUniformImage(ax, interpolation=interp, extent=(-4, 4, -4, 4), cmap=cm.Purples)
im.set_data(x, y, z)
ax.images.append(im)
ax.set_xlim(-4, 4)
ax.set_ylim(-4, 4)
ax.set_title(interp)

ax = axs[1, 1]
im = NonUniformImage(ax, interpolation=interp, extent=(-64, 64, -4, 4), cmap=cm.Purples)
im.set_data(x2, y, z)
ax.images.append(im)
ax.set_xlim(-64, 64)
ax.set_ylim(-4, 4)
ax.set_title(interp)

plt.show()
You can specify whether images should be plotted with the array origin $x[0,0]$ in the upper left or upper right by using the origin parameter. You can also control the default by setting image.origin in your matplotlibrc file; see http://matplotlib.org/matplotlibrc

```python
import matplotlib.pyplot as plt
import numpy as np

x = np.arange(120)
x.shape = (10, 12)

interp = 'bilinear'
fig, axs = plt.subplots(nrows=2, sharex=True, figsize=(3, 5))
axs[0].set_title('blue should be up')
axs[0].imshow(x, origin='upper', interpolation=interp)

axs[1].set_title('blue should be down')
axs[1].imshow(x, origin='lower', interpolation=interp)
```
```python
from __future__ import print_function
import numpy
import matplotlib.pyplot as plt

class IndexTracker(object):
    def __init__(self, ax, X):
        self.ax = ax
        ax.set_title('use scroll wheel to navigate images')

        self.X = X
        rows, cols, self.slices = X.shape
        self.ind = self.slices//2

        self.im = ax.imshow(self.X[:, :, self.ind])
        self.update()
```

98.105  *pylab_examples* example code: `image_slices_viewer.py`
```python
def onscroll(self, event):
    print("%s %s" % (event.button, event.step))
    if event.button == 'up':
        self.ind = numpy.clip(self.ind + 1, 0, self.slices - 1)
    else:
        self.ind = numpy.clip(self.ind - 1, 0, self.slices - 1)
    self.update()

def update(self):
    self.im.set_data(self.X[:, :, self.ind])
    ax.set_ylabel('slice %s' % self.ind)
    self.im.axes.figure.canvas.draw()

fig, ax = plt.subplots(1, 1)
X = numpy.random.rand(20, 20, 40)
tracker = IndexTracker(ax, X)

fig.canvas.mpl_connect('scroll_event', tracker.onscroll)
plt.show()
```

def bullseye_plot(ax, data, segBold=None, cmap=None, norm=None):
    """
    Bullseye representation for the left ventricle.
    """
    Parameters
    ----------
    ax : axes
    data : list of int and float
        The intensity values for each of the 17 segments
    segBold: list of int, optional
        A list with the segments to highlight
    cmap : ColorMap or None, optional
        Optional argument to set the desired colormap
    norm : Normalize or None, optional
        Optional argument to normalize data into the [0.0, 1.0] range

    Notes
    -----  
    This function create the 17 segment model for the left ventricle according
to the American Heart Association (AHA) [1]

plt.gca().set_yticklabels([])
Demonstrate how to use major and minor tickers.

The two relevant userland classes are Locators and Formatters. Locators determine where the ticks are and formatters control the formatting of ticks.

Minor ticks are off by default (NullLocator and NullFormatter). You can turn minor ticks on w/o labels by setting the minor locator. You can also turn labeling on for the minor ticker by setting the minor formatter.

Make a plot with major ticks that are multiples of 20 and minor ticks that are multiples of 5. Label major ticks with %d formatting but don’t label minor ticks.
The MultipleLocator ticker class is used to place ticks on multiples of some base. The FormatStrFormatter uses a string format string (e.g., \%d' or \%1.2f or \%1.1f cm') to format the tick.

The pyplot interface grid command changes the grid settings of the major ticks of the y and y axis together. If you want to control the grid of the minor ticks for a given axis, use for example

    ax.xaxis.grid(True, which='minor')

Note, you should not use the same locator between different Axis because the locator stores references to the Axis data and view limits.

---

```python
import matplotlib.pyplot as plt
import numpy as np
from matplotlib.ticker import MultipleLocator, FormatStrFormatter

majorLocator = MultipleLocator(20)
majorFormatter = FormatStrFormatter('%d')
minorLocator = MultipleLocator(5)

import matplotlib.pyplot as plt
import numpy as np
from matplotlib.ticker import MultipleLocator, FormatStrFormatter

majorLocator = MultipleLocator(20)
majorFormatter = FormatStrFormatter('%d')
majorLocator = MultipleLocator(5)

fig, ax = plt.subplots()
plt.plot(t, s)

ax.xaxis.set_major_locator(majorLocator)
ax.xaxis.set_major_formatter(majorFormatter)

# for the minor ticks, use no labels; default NullFormatter
ax.xaxis.set_minor_locator(minorLocator)

plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
Automatic tick selection for major and minor ticks.

Use interactive pan and zoom to see how the tick intervals change. There will be either 4 or 5 minor tick intervals per major interval, depending on the major interval.

```python
import numpy as np
import matplotlib.pyplot as plt
from matplotlib.ticker import AutoMinorLocator

# One can supply an argument to AutoMinorLocator to
# specify a fixed number of minor intervals per major interval, e.g.:
# minorLocator = AutoMinorLocator(2)
# would lead to a single minor tick between major ticks.

minorLocator = AutoMinorLocator()

t = np.arange(0.0, 100.0, 0.01)
s = np.sin(2*np.pi*t)*np.exp(-t*0.01)
```

markevery=0.1
This example demonstrates the various options for showing a marker at a subset of data points using the `markevery` property of a Line2D object.

Integer arguments are fairly intuitive. e.g. `markevery=5` will plot every 5th marker starting from the first data point.

Float arguments allow markers to be spaced at approximately equal distances along the line. The theoretical distance along the line between markers is determined by multiplying the display-coordinate distance of the axes bounding-box diagonal by the value of `markevery`. The data points closest to the theoretical distances will be shown.

A slice or list/array can also be used with `markevery` to specify the markers to show.

```python
from __future__ import division
import numpy as np
import matplotlib.pyplot as plt
```
import matplotlib.gridspec as gridspec

# define a list of markevery cases to plot
cases = [None,
         8,
         (30, 8),
         [16, 24, 30], [0, -1],
         slice(100, 200, 3),
         0.1, 0.3, 1.5,
         (0.0, 0.1), (0.45, 0.1)]

# define the figure size and grid layout properties
figsize = (10, 8)

ax2.set_ylim(y0, y1)

segs = []
for i in range(numRows):
    segs.append(np.hstack((t[:, np.newaxis], data[:, i, np.newaxis])))
    ticklocs.append(i * dr)

offsets = np.zeros((numRows, 2), dtype=float)
offsets[:, 1] = ticklocs

lines = LineCollection(segs, offsets=offsets, transOffset=None)
ax2.add_collection(lines)

# Set the yticks to use axes coordinates on the y axis
ax2.set_yticks(ticklocs)
ax2.set_yticklabels(['PG3', 'PG5', 'PG7', 'PG9'])

ax2.set_xlabel('Time (s)')

plt.tight_layout()
plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
Multiple images

```python
from matplotlib.pyplot import figure, show, axes, sci
from matplotlib import cm, colors
from matplotlib.font_manager import FontProperties
from numpy import amin, amax, ravel
from numpy.random import rand

Nr = 3
Nc = 2

fig = figure()
cmap = cm.cool

figtitle = 'Multiple images'
t = fig.text(0.5, 0.95, figtitle,
            horizontalalignment='center',
            fontproperties=FontProperties(size=16))
```

Make a set of images with a single colormap, norm, and colorbar.

It also illustrates colorbar tick labelling with a multiplier.

---

2588 Chapter 98. pylab_examples Examples
Matplotlib, Release 2.0.0

ax1.grid(True)
ax1.set_ylim(yrange)

plt.show()

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
This is a ported version of a MATLAB example from the signal processing toolbox that showed some difference at one time between Matplotlib's and MATLAB's scaling of the PSD. This differs from psd_demo3.py in that this uses a complex signal, so we can see that complex PSD's work properly.

```python
import numpy as np
import matplotlib.pyplot as plt
import matplotlib.mlab as mlab

prng = np.random.RandomState(123456)  # to ensure reproducibility

fs = 1000
f = np.linspace(0, 0.3, 301)
A = np.linspace([2, 8]).reshape(-1, 1)
B = np.linspace([150, 140]).reshape(-1, 1)
xn = (A * np.exp(2j * np.pi * f * t)).sum(axis=0) + 5 * prng.randn(*f.shape)

fig, (ax0, ax1) = plt.subplots(ncols=2)

ax0.plot(xn)
ax0.set_xlabel('Frequency (Hz)')
ax0.set_ylabel('Power Spectral Density (dB/Hz)')

ax1.plot(xn)
ax1.set_xlabel('Frequency (Hz)')
ax1.set_ylabel('Power Spectral Density (dB/Hz)')
```

This differs from psd_demo3.py in that this uses a complex signal, so we can see that complex PSD's work properly.
fig.subplots_adjust(hspace=0.45, wspace=0.3)
yticks = np.arange(-50, 30, 10)
yrange = (yticks[0], yticks[-1])
xticks = np.arange(-500, 550, 200)

ax0.psd(xn, NFFT=301, Fs=fs, window=mlab.window_none, pad_to=1024,
scale_by_freq=True)
ax0.set_title('Periodogram')
ax0.set_yticks(yticks)
ax0.set_xticks(xticks)
ax0.grid(True)
ax0.set_ymid(yrange)

ax1.psd(xn, NFFT=150, Fs=fs, window=mlab.window_none, pad_to=512, noverlap=75,
scale_by_freq=True)
ax1.set_title('Welch')
ax1.set_xticks(xticks)
ax1.set_yticks(yticks)
ax1.set_ylabel('') # overwrite the y-label added by `psd`
ax1.grid(True)
ax1.set_ymid(yrange)

plt.show()
Some people prefer to write more pythonic, object-oriented code rather than use the pyplot interface to matplotlib. This example shows you how.

Unless you are an application developer, I recommend using part of the pyplot interface, particularly the figure, close, subplot, axes, and show commands. These hide a lot of complexity from you that you don’t need to see in normal figure creation, like instantiating DPI instances, managing the bounding boxes of the figure elements, creating and realizing GUI windows and embedding figures in them.

If you are an application developer and want to embed matplotlib in your application, follow the lead of examples/embedding_in_wx.py, examples/embedding_in_gtk.py or examples/embedding_in_tk.py. In this case you will want to control the creation of all your figures, embedding them in application windows, etc.

If you are a web application developer, you may want to use the example in webapp_demo.py, which shows how to use the backend agg figure canvas directly, with none of the globals (current figure,
current axes) that are present in the pyplot interface. Note that there is no reason why the pyplot interface won't work for web application developers, however.

If you see an example in the examples dir written in pyplot interface, and you want to emulate that using the true python method calls, there is an easy mapping. Many of those examples use 'set' to control figure properties. Here's how to map those commands onto instance methods

The syntax of set is

\[
\text{plt.setp(object or sequence, somestring, attribute)}
\]

if called with an object, set calls

\[
\text{object.set_somestring(attribute)}
\]

if called with a sequence, set does

\[
\text{for object in sequence:}
\]
\[
\text{object.set_somestring(attribute)}
\]

So for your example, if a is your axes object, you can do

\[
\text{a.set_xticklabels([])}
\]
\[
\text{a.set_yticklabels([])}
\]
\[
\text{a.set_xticks([])}
\]
\[
\text{a.set_yticks([])}
\]

```python
from matplotlib.pyplot import figure, show
from numpy import arange, sin, pi

t = arange(0.0, 1.0, 0.01)
fig = figure(1)
ax1 = fig.add_subplot(211)
ax1.plot(t, sin(2*pi*t))
ax1.grid(True)
ax1.set_ylim((-2, 2))
ax1.set_ylabel('1 Hz')
ax1.set_title('A sine wave or two')
for label in ax1.get_xticklabels():
    label.set_color('r')

ax2 = fig.add_subplot(212)
ax2.plot(t, sin(2*2*pi*t))
ax2.grid(True)
```
ax2.set_ylim((-2, 2))
l = ax2.set_xlabel('Hi mom')
l.set_color('g')
l.set_fontsize('large')

show()

pivot='mid'; every third arrow; units='inches'
triangular head; scale with x view; black edges
Demonstration of quiver and quiverkey functions. This is using the new version coming from the code in quiver.py.

Known problem: the plot autoscaling does not take into account the arrows, so those on the boundaries are often out of the picture. This is *not* an easy problem to solve in a perfectly general way. The workaround is to manually expand the axes.

```python
import matplotlib.pyplot as plt
import numpy as np
from numpy import ma

X, Y = np.meshgrid(np.arange(0, 2 * np.pi, .2), np.arange(0, 2 * np.pi, .2))

from matplotlib import pyplot as plt
import numpy as np
import matplotlib

x = np.arange(0.0, 50.0, 2.0)
y = x ** 1.3 + np.random.rand(*x.shape) * 30.0
The pyplot interface allows you to use `setp` and `getp` to set and get object properties, as well as to do introspection on the object.

**set:**
To set the linestyle of a line to be dashed, you can do

```python
g >> line, = plt.plot([1,2,3])
```
>>> plt.setp(line, linestyle='--')

If you want to know the valid types of arguments, you can provide the name of the property you want to set without a value

>>> plt.setp(line, 'linestyle')
   linestyle: ['-' | '--' | '-.' | ':' | 'steps' | 'None']

If you want to see all the properties that can be set, and their possible values, you can do

>>> plt.setp(line)

set operates on a single instance or a list of instances. If you are in query mode introspecting the possible values, only the first instance in the sequence is used. When actually setting values, all the instances will be set. e.g., suppose you have a list of two lines, the following will make both lines thicker and red

>>> x = np.arange(0,1.0,0.01)
>>> y1 = np.sin(2*np.pi*x)
>>> y2 = np.sin(4*np.pi*x)
>>> lines = plt.plot(x, y1, x, y2)
>>> plt.setp(lines, linewidth=2, color='r')

get:

get returns the value of a given attribute. You can use get to query the value of a single attribute

>>> plt.getp(line, 'linewidth')
   0.5

or all the attribute/value pairs

>>> plt.getp(line)
   aa = True
   alpha = 1.0
   antialiased = True
   c = b
   clip_on = True
   color = b
   ... long listing skipped ...

Aliases:

To reduce keystrokes in interactive mode, a number of properties have short aliases, e.g., 'lw' for 'linewidth' and 'mec' for 'markeredgecolor'. When calling set or get in introspection mode, these properties will be listed as 'fullname or aliasname', as in

98.166  pylab_examples example code: shared_axis_across_figures.py
connect the data limits on the axes in one figure with the axes in another. This is not the right way to do this for two axes in the same figure -- use the sharex and sharey property in that case

```python
import numpy as np
import matplotlib.pyplot as plt

fig1 = plt.figure()
fig2 = plt.figure()

ax1 = fig1.add_subplot(111)
ax2 = fig2.add_subplot(111, sharex=ax1, sharey=ax1)

ax1.plot(np.random.rand(100), 'o')
ax2.plot(np.random.rand(100), 'o')

# In the latest release, it is no longer necessary to do anything special to share axes across figures:

# ax1.sharex_foreign(ax2)
# ax2.sharex_foreign(ax1)

# ax2.sharey_foreign(ax1)
# ax2.sharey_foreign(ax1)
```
You can share the x or y axis limits for one axis with another by passing an axes instance as a sharex or sharey kwarg.

Changing the axis limits on one axes will be reflected automatically in the other, and vice-versa, so when you navigate with the toolbar the axes will follow each other on their shared axes. Ditto for changes in the axis scaling (e.g., log vs linear). However, it is possible to have differences in tick labeling, e.g., you can selectively turn off the tick labels on one axes.

The example below shows how to customize the tick labels on the various axes. Shared axes share the tick locator, tick formatter, view limits, and transformation (e.g., log, linear). But the ticklabels themselves do not share properties. This is a feature and not a bug, because you may want to make the tick labels smaller on the upper
axes, e.g., in the example below.

If you want to turn off the ticklabels for a given axes (e.g., on subplot(211) or subplot(212), you cannot do the standard trick

```
setp(ax2, xticklabels=[])  
```

because this changes the tick Formatter, which is shared among all axes. But you can alter the visibility of the labels, which is a property

```
setp(ax2.get_xticklabels(), visible=False)
```

```
import matplotlib.pyplot as plt
import numpy as np

# Generates the data

t = np.arange(0.01, 5.0, 0.01)
s1 = np.sin(2*np.pi*t)
s2 = np.exp(-t)
s3 = np.sin(4*np.pi*t)

ax1 = plt.subplot(311)
plt.plot(t, s1)
plt.setp(ax1.get_xticklabels(), fontsize=6)

# share x only
ax2 = plt.subplot(312, sharex=ax1)
plt.plot(t, s2)
plt.setp(ax2.get_xticklabels(), visible=False)

# share x and y
ax3 = plt.subplot(313, sharex=ax1, sharey=ax1)
plt.plot(t, s3)
plt.xlim(0.01, 5.0)
plt.show()

Sharing x per column, y per row

![Graphs showing sharing x per column, y per row]
Examples illustrating the use of plt.subplots().

This function creates a figure and a grid of subplots with a single call, while providing reasonable control over how the individual plots are created. For very refined tuning of subplot creation, you can still use add_subplot() directly on a new figure.

```python
import matplotlib.pyplot as plt
import numpy as np

# Simple data to display in various forms
x = np.linspace(0, 2 * np.pi, 400)
y = np.sin(x ** 2)

plt.close('all')

# Just a figure and one subplot
f, ax = plt.subplots()
ax.plot(x, y)
ax.set_title('Simple plot')

# Two subplots, the axes array is 1-d
f, axarr = plt.subplots(2, sharex=True)
axarr[0].plot(x, y)
axarr[0].set_title('Sharing X axis')
```
```
axarr[1].scatter(x, y)

# Two subplots, unpack the axes array immediately
f, (ax1, ax2) = plt.subplots(1, 2, sharey=True)
ax1.plot(x, y)
ax1.set_title('Sharing Y axis')
ax2.scatter(x, y)

# Three subplots sharing both x/y axes
f, (ax1, ax2, ax3) = plt.subplots(3, sharex=True, sharey=True)
ax1.plot(x, y)
ax1.set_title('Sharing both axes')
ax2.scatter(x, y)
ax3.scatter(x, 2 * y ** 2 - 1, color='r')

# Fine-tune figure; make subplots close to each other and hide x ticks for
# all but bottom plot.
f.subplots_adjust(hspace=0)
plt.setp([a.get_xticklabels() for a in f.axes[:-1]], visible=False)

# row and column sharing
f, ((ax1, ax2), (ax3, ax4)) = plt.subplots(2, 2, sharex='col', sharey='row')
ax1.plot(x, y)
ax1.set_title('Sharing x per column, y per row')
ax2.scatter(x, y)
ax3.scatter(x, 2 * y ** 2 - 1, color='r')
ax4.plot(x, 2 * y ** 2 - 1, color='r')

# Four axes, returned as a 2-d array
f, axarr = plt.subplots(2, 2)
axarr[0, 0].plot(x, y)

plt.show()
You can use TeX to render all of your matplotlib text if the rc parameter text.usetex is set. This works currently on the agg and ps backends, and requires that you have tex and the other dependencies described at http://matplotlib.org/users/usetex.html properly installed on your system. The first time you run a script you will see a lot of output from tex and associated tools. The next time, the run may be silent, as a lot of the information is cached in ~/.tex.cache

import numpy as np
import matplotlib.pyplot as plt

plt.rc('text', usetex=True)

```
Fun with text!
```

```
f(t) = exp(-t) sin(2 pi t)
```

Controlling the properties of axis text using handles

See examples/text_themes.py for a more elegant, pythonic way to control fonts. After all, if we were slaves to MATLAB, we wouldn't be using python!
import matplotlib.pyplot as plt
import numpy as np

def f(t):
    s1 = np.sin(2*np.pi*t)
    e1 = np.exp(-t)
    return np.multiply(s1, e1)

t1 = np.arange(0.0, 5.0, 0.1)
t2 = np.arange(0.0, 5.0, 0.02)

fig, ax = plt.subplots()
plt.plot(t1, f(t1), 'bo', t2, f(t2), 'k')
plt.text(3.0, 0.6, r'$f(t) = \exp(-t) \sin(2\pi t)$')
ttext = plt.title('Fun with text!')
ytext = plt.ylabel('Damped oscillation')
xtext = plt.xlabel('time (s)')

plt.setp(ttext, size='large', color='r', style='italic')
plt.setp(xtext, size='medium', name=['Courier', 'DejaVu Sans Mono'],
         weight='bold', color='g')
plt.setp(ytext, size='medium', name=['Helvetica', 'DejaVu Sans'],
         weight='light', color='b')
plt.show()
The way matplotlib does text layout is counter-intuitive to some, so this example is designed to make it a little clearer. The text is aligned by it’s bounding box (the rectangular box that surrounds the ink rectangle). The order of operations is basically rotation then alignment, rather than alignment then rotation. Basically, the text is centered at your x,y location, rotated around this point, and then aligned according to the bounding box of the rotated text.

So if you specify left, bottom alignment, the bottom left of the bounding box of the rotated text will be at the x,y coordinate of the text.

But a picture is worth a thousand words!

```python
import matplotlib.pyplot as plt
import numpy as np

def addtext(props):
    plt.text(0.5, 0.5, 'text 0', props, rotation=0)
```

```python
plt.text(1.5, 0.5, 'text 45', props, rotation=45)
plt.text(2.5, 0.5, 'text 135', props, rotation=135)
plt.text(3.5, 0.5, 'text 225', props, rotation=225)
plt.text(4.5, 0.5, 'text -45', props, rotation=-45)
plt.yticks([0, .5, 1])
plt.grid(True)

# the text bounding box
bbox = {'fc': '0.8', 'pad': 0}

plt.subplot(211)
addtext({'ha': 'center', 'va': 'center', 'bbox': bbox})
plt.xlim(0, 5)
plt.xticks(np.arange(0, 5.1, 0.5), [])
plt.ylabel('center / center')

plt.subplot(212)
addtext({'ha': 'left', 'va': 'bottom', 'bbox': bbox})
plt.xlim(0, 5)
plt.xticks(np.arange(0, 5.1, 0.5))
plt.ylabel('left / bottom')
plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
Text objects in matplotlib are normally rotated with respect to the
screen coordinate system (i.e., 45 degrees rotation plots text along a
line that is in between horizontal and vertical no matter how the axes
are changed). However, at times one wants to rotate text with respect
to something on the plot. In this case, the correct angle won’t be
the angle of that object in the plot coordinate system, but the angle
that that object APPEARS in the screen coordinate system. This angle
is found by transforming the angle from the plot to the screen
coordinate system, as shown in the example below.

```python
import matplotlib.pyplot as plt
import numpy as np

# Plot diagonal line (45 degrees)
h = plt.plot(np.arange(0, 10), np.arange(0, 10))

# set limits so that it no longer looks on screen to be 45 degrees
plt.xlim([-10, 20])

# Locations to plot text
```

"""
"""
```python
l1 = np.array((1, 1))
l2 = np.array((5, 5))

# Rotate angle
angle = 45
trans_angle = plt.gca().transData.transform_angles(np.array((45,)),
                                                    l2.reshape((1, 2)))[0]

98.191 pylab_examples example code: toggle_images.py

```
"""
"""
toggle between two images by pressing "t"
The basic idea is to load two images (they can be different shapes) and plot them to the same axes. Then, toggle the visible property of them using keypress event handling
```

98.191. pylab_examples example code: toggle_images.py
If you want two images with different shapes to be plotted with the same extent, they must have the same "extent" property.

As usual, we'll define some random images for demo. Real data is much more exciting!

Note, on the wx backend on some platforms (e.g., linux), you have to first click on the figure before the keypress events are activated. If you know how to fix this, please email us!

```python
import matplotlib.pyplot as plt
import numpy as np

# two images x1 is initially visible, x2 is not
x1 = np.random.random((100, 100))
x2 = np.random.random((150, 175))

# arbitrary extent - both images must have same extent if you want
# them to be resampled into the same axes space
extent = (0, 1, 0, 1)
im1 = plt.imshow(x1, extent=extent)
im2 = plt.imshow(x2, extent=extent)
im2.set_visible(False)

def toggle_images(event):
    'toggle the visible state of the two images'
    if event.key != 't':
        return
    b1 = im1.get_visible()
b2 = im2.get_visible()
im1.set_visible(not b1)
im2.set_visible(not b2)
plt.draw()

plt.connect('key_press_event', toggle_images)
plt.show()
```

98.192  `pylab_examples` example code: `transoffset.py`
This illustrates the use of transforms.offset_copy to make a transform that positions a drawing element such as a text string at a specified offset in screen coordinates (dots or inches) relative to a location given in any coordinates.

Every Artist—the mpl class from which classes such as Text and Line are derived—has a transform that can be set when the Artist is created, such as by the corresponding pyplot command. By default this is usually the Axes.transData transform, going from data units to screen dots. We can use the offset_copy function to make a modified copy of this transform, where the modification consists of an offset.

```python
import matplotlib.pyplot as plt
import matplotlib.transforms as mtrans
import numpy as np
from matplotlib.transforms import offset_copy

xs = np.arange(7)
ys = xs**2

fig = plt.figure(figsize=(5, 10))
ax = plt.subplot(2, 1, 1)

# If we want the same offset for each text instance, # we only need to make one transform. To get the # transform argument to offset_copy, we need to make the axes # first; the subplot command above is one way to do this.
trans_offset = mtrans.offset_copy(ax.transData, fig=fig, x=0.05, y=0.10, units='inches')

for x, y in zip(xs, ys):
    plt.plot((x,), (y,), 'ro')
    plt.text(x, y, '%d,%d' % (int(x), int(y)), transform=trans_offset)

# offset_copy works for polar plots also.
ax = plt.subplot(2, 1, 2, projection='polar')

trans_offset = mtrans.offset_copy(ax.transData, fig=fig, y=6, units='dots')

for x, y in zip(xs, ys):
    plt.polar((x,), (y,), 'ro')
    plt.text(x, y, '%d,%d' % (int(x), int(y)), transform=trans_offset, horizontalalignment='center', verticalalignment='bottom')
```
Contour plot of Delaunay triangulation

98.193 pylab_examples example code: tricontour_demo.py
Contour plots of unstructured triangular grids.

```python
import matplotlib.pyplot as plt
import matplotlib.tri as tri
import numpy as np
import math

# Creating a Triangulation without specifying the triangles results in the
# Delaunay triangulation of the points.

# First create the x and y coordinates of the points.
n_angles = 48
n_radii = 8
min_radius = 0.25
radii = np.linspace(min_radius, 0.95, n_radii)
angles = np.linspace(0, 2*math.pi, n_angles, endpoint=False)
angles = np.repeat(angles[..., np.newaxis], n_radii, axis=1)
angles[:, 1::2] += math.pi/n_angles
x = (radii*np.cos(angles)).flatten()
y = (radii*np.sin(angles)).flatten()
z = (np.cos(radii)*np.cos(angles*3.0)).flatten()

# Create the Triangulation; no triangles so Delaunay triangulation created.
```

Contour plot of user-specified triangulation

```
```python
triang = tri.Triangulation(x, y)

# Mask off unwanted triangles.
xmid = x[triang.triangles].mean(axis=1)
ymid = y[triang.triangles].mean(axis=1)
mask = np.where(xmid*xmid + ymid*ymid < min_radius*min_radius, 1, 0)
triang.set_mask(mask)

# pcolor plot.
plt.figure()
plt.gca().set_aspect('equal')
plt.tricontourf(triang, z)
plt.colorbar()
plt.tricontour(triang, z, colors='k')
plt.title('Contour plot of Delaunay triangulation')

# You can specify your own triangulation rather than perform a Delaunay
# triangulation of the points, where each triangle is given by the indices of
# the three points that make up the triangle, ordered in either a clockwise or
# anticlockwise manner.

2712 Chapter 98. pylab_examples Examples
### Code Snippet

```python
# Rather than create a Triangulation object, can simply pass x, y and triangles
# arrays to tripcolor directly. It would be better to use a Triangulation
# object if the same triangulation was to be used more than once to save
# duplicated calculations.
plt.figure()
plt.gca().set_aspect('equal')
plt.tricontourf(x, y, triangles, z)
plt.colorbar()
plt.title('Contour plot of user-specified triangulation')
plt.xlabel('Longitude (degrees)')
plt.ylabel('Latitude (degrees)')
plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
Filtering a Delaunay mesh
(application to high-resolution tricontouring)

Demonstrates high-resolution tricontouring of a random set of points; a matplotlib.tri.TriAnalyzer is used to improve the plot quality.

The initial data points and triangular grid for this demo are:
- a set of random points is instantiated, inside [-1, 1] x [-1, 1] square.
- A Delaunay triangulation of these points is then computed, of which a random subset of triangles is masked out by the user (based on *init_mask_frac* parameter). This simulates invalidated data.

The proposed generic procedure to obtain a high resolution contouring of such a data set is the following:
1) Compute an extended mask with a matplotlib.tri.TriAnalyzer, which will exclude badly shaped (flat) triangles from the border of the triangulation. Apply the mask to the triangulation (using set_mask).
2) Refine and interpolate the data using a matplotlib.tri.UniformTriRefiner.
3) Plot the refined data with tricontour.

```python
from matplotlib.tri import Triangulation, TriAnalyzer, UniformTriRefiner
import matplotlib.pyplot as plt

```
Matplotlib, Release 2.0.0

import matplotlib.cm as cm
import numpy as np

# Analytical test function

def experiment_res(x, y):
    """An analytic function representing experiment results """
    x = 2.*x
    r1 = np.sqrt((0.5 - x)**2 + (0.5 - y)**2)
    thet1 = np.arctan2(0.5 - x, 0.5 - y)
    r2 = np.sqrt((-x - 0.2)**2 + (-y - 0.2)**2)
    thet2 = np.arctan2(-x - 0.2, -y - 0.2)
    z = (4*(np.exp((r1/10)**2) - 1)*30. * np.cos(3*thet1) +
        (np.exp((r2/10)**2) - 1)*30. * np.cos(5*thet2) +
        2*(x**2 + y**2))
    return (np.max(z) - z)/(np.max(z) - np.min(z))

It is also worth noting that, because matplotlib can save figures to file-like object, matplotlib can also be used inside a cgi-script *without* needing to write a figure to disk.

```
from matplotlib.backends.backend_agg import FigureCanvasAgg
from matplotlib.figure import Figure
import numpy as np

def make_fig():
    ""
    Make a figure and save it to "webagg.png".
    ""
    fig = Figure()
    ax = fig.add_subplot(1, 1, 1)

    ax.plot([1, 2, 3], 'ro--', markersize=12, markerfacecolor='g')

    # make a translucent scatter collection
    x = np.random.rand(100)
y = np.random.rand(100)
area = np.pi * (10 * np.random.rand(100)) ** 2  # 0 to 10 point radii
c = ax.scatter(x, y, area)
c.set_alpha(0.5)

    # add some text decoration
    ax.set_title('My first image')
    ax.set_ylabel('Some numbers')
    ax.set_xticks((.2, .4, .6, .8))
    labels = ax.set_xticklabels(('Bill', 'Fred', 'Ted', 'Ed'))

    # To set object properties, you can either iterate over the
    # objects manually, or define you own set command, as in setapi
    # above.
    for label in labels:
        label.set_rotation(45)
        label.set_fontsize(12)

    FigureCanvasAgg(fig).print_png('webapp.png', dpi=150)

make_fig()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
import matplotlib.pyplot as plt
import numpy as np

np.random.seed(0)

x, y = np.random.randn(2, 100)
fig = plt.figure()

The default drawing order for axes is patches, lines, text. This order is determined by the zorder attribute. The following defaults are set:

<table>
<thead>
<tr>
<th>Artist</th>
<th>Z-order</th>
</tr>
</thead>
<tbody>
<tr>
<td>Patch / PatchCollection</td>
<td>1</td>
</tr>
<tr>
<td>Line2D / LineCollection</td>
<td>2</td>
</tr>
<tr>
<td>Text</td>
<td>3</td>
</tr>
</tbody>
</table>

You can change the order for individual artists by setting the zorder. Any individual plot() call can set a value for the zorder of that particular item.

In the first subplot below, the lines are drawn above the patch collection from the scatter, which is the default.

In the subplot below, the order is reversed.

The second figure shows how to control the zorder of individual lines.

import matplotlib.pyplot as plt
import numpy as np

x = np.random.random(20)
y = np.random.random(20)
```python
# Lines on top of scatter
plt.figure()
plt.subplot(211)
plt.plot(x, y, 'r', lw=3)
plt.scatter(x, y, s=120)
plt.title('Lines on top of dots')

# Scatter plot on top of lines
plt.subplot(212)
plt.plot(x, y, 'r', zorder=1, lw=3)
plt.scatter(x, y, s=120, zorder=2)
plt.title('Dots on top of lines')

# A new figure, with individually ordered items
x = np.linspace(0, 2*np.pi, 100)
plt.figure()
plt.plot(x, np.sin(x), linewidth=10, color='black', label='zorder=10', zorder=10)  # on top
plt.plot(x, np.cos(1.3*x), linewidth=10, color='red', label='zorder=1', zorder=1)  # on bottom
plt.plot(x, np.sin(2.1*x), linewidth=10, color='green', label='zorder=3', zorder=3)
plt.axhline(0, linewidth=10, color='blue', label='zorder=2', zorder=2)
plt.title('Custom order of elements')
l = plt.legend()

### 99.20 pyplots example code: tex_demo.py

[source code]

```python
# Demo of TeX rendering.

You can use TeX to render all of your matplotlib text if the rc parameter text.usetex is set. This works currently on the agg and ps backends, and requires that you have tex and the other dependencies described at http://matplotlib.org/users/usetex.html properly installed on your system. The first time you run a script you will see a lot of output from tex and associated tools. The next time, the run may be silent, as a lot of the information is cached in ~/.tex.cache

```import numpy as np
import matplotlib.pyplot as plt

# Example data

Chapter 102. showcase Examples


Shaded & power normalized rendering

The Mandelbrot set rendering can be improved by using a normalized recount associated with a power normalized colormap (\(\texttt{gamma=0.3}\)). Rendering can be further enhanced thanks to shading.

The `maxiter` gives the precision of the computation. `\texttt{maxiter=200}` should take a few seconds on most modern laptops.

```python
import numpy as np

def mandelbrot_set(xmin, xmax, ymin, ymax, xn, yn, maxiter, horizon=2.0):
    X = np.linspace(xmin, xmax, xn, dtype=np.float32)
    # Further code here...
```
```python
Y = np.linspace(ymin, ymax, yn, dtype=np.float32)
C = X + Y[:, None]*1j
N = np.zeros(C.shape, dtype=int)
Z = np.zeros(C.shape, np.complex64)
for n in range(maxiter):
    I = np.less(abs(Z), horizon)
    N[I] = n
    Z[I] = Z[I]**2 + C[I]
N[N == maxiter-1] = 0
return Z, N

if __name__ == '__main__':
    import time
    import matplotlib
    from matplotlib import colors
    import matplotlib.pyplot as plt
    xmin, xmax, xn = -2.25, +0.75, 3000/2
    ymin, ymax, yn = -1.25, +1.25, 2500/2
    maxiter = 200
    horizon = 2.0 ** 40
    log_horizon = np.log(np.log(horizon))/np.log(2)
    Z, N = mandelbrot_set(xmin, xmax, ymin, ymax, xn, yn, maxiter, horizon)

    # Normalized recount as explained in:
    # https://linas.org/art-gallery/escape/smooth.html

    # This line will generate warnings for null values but it is faster to
    # process them afterwards using the nan_to_num
    with np.errstate(invalid='ignore'):
        M = np.nan_to_num(N + 1 -
                          np.log(np.log(abs(Z)))/np.log(2) +
                          log_horizon)

    dpi = 72
    width = 10
    height = 10*yn/xn
    fig = plt.figure(figsize=(width, height), dpi=dpi)
    ax = fig.add_axes([0.0, 0.0, 1.0, 1.0], frameon=False, aspect=1)

103.2 specialty_plots example code: hinton_demo.py

Demo of a function to create Hinton diagrams.
Hinton diagrams are useful for visualizing the values of a 2D array (e.g. a weight matrix): Positive and negative values are represented by white and black squares, respectively, and the size of each square represents the magnitude of each value.

Initial idea from David Warde-Farley on the SciPy Cookbook

```python
import numpy as np
import matplotlib.pyplot as plt

def hinton(matrix, max_weight=None, ax=None):
    """Draw Hinton diagram for visualizing a weight matrix."""
    ax = ax if ax is not None else plt.gca()

    if not max_weight:
        max_weight = 2 ** np.ceil(np.log(np.abs(matrix).max()) / np.log(2))

    ax.patch.set_facecolor('gray')
    ax.set_aspect('equal', 'box')
    ax.xaxis.set_major_locator(plt.NullLocator())
    ax.yaxis.set_major_locator(plt.NullLocator())

    for (x, y), w in np.ndenumerate(matrix):
        color = 'white' if w > 0 else 'black'
        size = np.sqrt(np.abs(w) / max_weight)
        rect = plt.Rectangle([x - size / 2, y - size / 2], size, size,
                             facecolor=color, edgecolor=color)
        ax.add_patch(rect)

    ax.autoscale_view()
    ax.invert_yaxis()

if __name__ == '__main__':
    hinton(np.random.rand(20, 20) - 0.5)
    plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
Demonstrates the visual effect of varying blend mode and vertical exaggeration on "hillshaded" plots.

Note that the "overlay" and "soft" blend modes work well for complex surfaces such as this example, while the default "hsv" blend mode works best for smooth
In most cases, hillshading is used purely for visual purposes, and \( *dx*/*dy* \) can be safely ignored. In that case, you can tweak \( *\text{vert}\_\text{exag}* \) (vertical exaggeration) by trial and error to give the desired visual effect. However, this example demonstrates how to use the \( *dx* \) and \( *dy* \) kwargs to ensure that the \( *\text{vert}\_\text{exag}* \) parameter is the true vertical exaggeration.

```python
import numpy as np
import matplotlib.pyplot as plt
from matplotlib.cbook import get_sample_data
from matplotlib.colors import LightSource
dem = np.load(get_sample_data('jacksboro_fault_dem.npz'))
z = dem['elevation']

#-- Optional dx and dy for accurate vertical exaggeration ---------------------
# If you need topographically accurate vertical exaggeration, or you don't want
# to guess at what \( *\text{vert}\_\text{exag}* \) should be, you'll need to specify the cellsize
# of the grid (i.e. the \( *dx* \) and \( *dy* \) parameters). Otherwise, any \( *\text{vert}\_\text{exag}* \)
# value you specify will be relative to the grid spacing of your input data
# (in other words, \( *dx* \) and \( *dy* \) default to 1.0, and \( *\text{vert}\_\text{exag}* \) is calculated
# relative to those parameters). Similarly, \( *dx* \) and \( *dy* \) are assumed to be in
# the same units as your input \( z \)-values. Therefore, we'll need to convert the
# given \( dx \) and \( dy \) from decimal degrees to meters.

dx, dy = dem['dx'], dem['dy']
dy = 111200 * dy
dx = 111200 * dx * np.cos(np.radians(dem['ymin']))

# Shade from the northwest, with the sun 45 degrees from horizontal
ls = LightSource(azdeg=315, altdeg=45)
cmap = plt.cm.gist_earth

fig, axes = plt.subplots(nrows=4, ncols=3, figsize=(8, 9))
plt.setp(axes.flat, xticks=[], yticks=[])  # Vary vertical exaggeration and blend mode and plot all combinations
for col, ve in zip(axes.T, [0.1, 1, 10]):
    # Show the hillshade intensity image in the first row
    col[0].imshow(ls.hillshade(z, vert_exag=ve, dx=dx, dy=dy), cmap='gray')

    # Place hillshaded plots with different blend modes in the rest of the rows
    for ax, mode in zip(col[1:], ['hsv', 'overlay', 'soft']):
        rgb = ls.shade(z, cmap=cmap, blend_mode=mode, vert_exag=ve, dx=dx, dy=dy)
        ax.imshow(rgb)

    # Label rows and columns
    for ax, ve in zip(axes[0], [0.1, 1, 10]):
        ax.set_title('{:.1f}'.format(ve), size=18)
    for ax, mode in zip(axes[:, 0], ['Hillshade', 'hsv', 'overlay', 'soft']):
        ax.set_ylabel(mode, size=18)
```

--snip--

Box plot vs. violin plot comparison
Note that although violin plots are closely related to Tukey's (1977) box plots, they add useful information such as the distribution of the sample data (density trace).

By default, box plots show data points outside $1.5 \times$ the inter-quartile range as outliers above or below the whiskers whereas violin plots show the whole range of the data.

A good general reference on boxplots and their history can be found here: http://vita.had.co.nz/papers/boxplots.pdf

Violin plots require matplotlib >= 1.4.

For more information on violin plots, the scikit-learn docs have a great section: http://scikit-learn.org/stable/modules/density.html

```python
import matplotlib.pyplot as plt
import numpy as np

fig, axes = plt.subplots(nrows=1, ncols=2, figsize=(9, 4))

# generate some random test data
all_data = [np.random.normal(0, std, 100) for std in range(6, 10)]

# plot violin plot
axes[0].violinplot(all_data,
    showmeans=False,
    showmedians=True)
axes[0].set_title('violin plot')

# plot box plot
axes[1].boxplot(all_data)
axes[1].set_title('box plot')

# adding horizontal grid lines
for ax in axes:
    ax.yaxis.grid(True)
    ax.set_xticks([y + 1 for y in range(len(all_data))])
    ax.set_xlabel('xlabel')
    ax.set_ylabel('ylabel')

# add x-tick labels
plt.setp(axes, xticks=[y + 1 for y in range(len(all_data))],
         xticklabels=['x1', 'x2', 'x3', 'x4'])
plt.show()

Demo of the errorbar function

This exhibits the most basic use of the error bar method.
In this case, constant values are provided for the error
in both the x- and y-directions.

```python
import numpy as np
import matplotlib.pyplot as plt

# example data
x = np.arange(0.1, 4, 0.5)
y = np.exp(-x)

fig, ax = plt.subplots()
ax.errorbar(x, y, xerr=0.2, yerr=0.4)
plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
Demo of the different ways of specifying error bars

Errors can be specified as a constant value (as shown in `errorbar_demo.py`). However, this example demonstrates how they vary by specifying arrays of error values.

If the raw `x` and `y` data have length N, there are two options:

Array of shape (N,):
    Error varies for each point, but the error values are symmetric (i.e. the lower and upper values are equal).

Array of shape (2, N):
    Error varies for each point, and the lower and upper limits (in that order) are different (asymmetric case)

In addition, this example demonstrates how to use log scale with error bars.
import numpy as np
import matplotlib.pyplot as plt

# example data
x = np.arange(0.1, 4, 0.5)
y = np.exp(-x)

# example error bar values that vary with x-position
error = 0.1 + 0.2 * x

fig, (ax0, ax1) = plt.subplots(nrows=2, sharex=True)
ax0.errorbar(x, y, yerr=error, fmt='-o')
ax0.set_title('variable, symmetric error')

# error bar values w/ different +/- errors that
# also vary with the x-position
lower_error = 0.4 * error
upper_error = error
asymmetric_error = [lower_error, upper_error]
ax1.errorbar(x, y, xerr=asymmetric_error, fmt='o')
ax1.set_title('variable, asymmetric error')
ax1.set_yscale('log')
plt.show()

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
**104.8 statistics example code: errorbar_limits.py**

```
1.0 1.5 2.0 2.5 3.0 3.5 4.0 4.5 5.0
0.0 0.5 1.0 1.5 2.0 2.5 3.0
```

In matplotlib, error bars can have "limits". Applying limits to the error bars essentially makes the error unidirectional. Because of that, upper and lower limits can be applied in both the y- and x-directions via the `xuplims`, `lolims`, `xuplims`, and `xlolims` parameters, respectively. These parameters can be scalar or boolean arrays.

For example, if `xlolims` is `True`, the x-error bars will only extend from the data towards increasing values. If `uplims` is an array filled with `False` except for the 4th and 7th values, all of the y-error bars will be bidirectional, except the 4th and 7th bars, which will extend from the data towards decreasing y-values.

```
import numpy as np
import matplotlib.pyplot as plt

# example data
x = np.array([0.5, 1.0, 1.5, 2.0, 2.5, 3.0, 3.5, 4.0, 4.5, 5.0])
y = np.exp(-x)
xerr = 0.1
yerr = 0.2
```

```
Matplotlib, Release 2.0.0

```python
# lower & upper limits of the error
lolims = np.array([0, 0, 1, 0, 0, 0, 1, 0, 1, 0], dtype=bool)
uplims = np.array([0, 1, 0, 0, 1, 0, 0, 0, 1, 0], dtype=bool)
ls = 'dotted'

            xlolims=xlolims, xuplims=xuplims,
            uplims=uplims, lolims=lolims,
            marker='o', markersize=8,
            linestyle='none')

# tidy up the figure
ax.set_xlim((0, 5.5))
ax.set_title('Errorbar upper and lower limits')
plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
Demo on creating boxes from error bars using PatchCollection

In this example, we snazz up a pretty standard error bar plot by adding a rectangle patch defined by the limits of the bars in both the x- and y-directions. To do this, we have to write our own custom function called `make_error_boxes`. Close inspection of this function will reveal the preferred pattern in writing functions for matplotlib:

1. an `Axes` object is passed directly to the function
2. the function operates on the `Axes` methods directly, not through the `pyplot` interface
3. plotting kwargs that could be abbreviated are spelled out for better code readability in the future (for example we use `facecolor` instead of `fc`)
4. the artists returned by the `Axes` plotting methods are then returned by the function so that, if desired, their styles can be modified later outside of the function (they are not modified in this example).
import numpy as np
import matplotlib.pyplot as plt
from matplotlib.collections import PatchCollection
from matplotlib.patches import Rectangle

# Number of data points
n = 5

# Dummy data
np.random.seed(10)
x = np.arange(0, n, 1)
y = np.random.randn(n) * 5.

# Dummy errors (above and below)
xerr = np.random.randn(2, n) + 0.1
yerr = np.random.randn(2, n) + 0.2

def make_error_boxes(ax, xdata, ydata, xerror, yerror, facecolor='r',
                      edgecolor='None', alpha=0.5):

    # Create list for all the error patches
    errorboxes = []

    # Loop over data points; create box from errors at each point
    for x, y, xe, ye in zip(xdata, ydata, xerror.T, yerror.T):
        rect = Rectangle((x - xe[0], y - ye[0]), xe.sum(), ye.sum())
        errorboxes.append(rect)

    # Create patch collection with specified colour/alpha
    pc = PatchCollection(errorboxes, facecolor=facecolor, alpha=alpha,
                         edgecolor=edgecolor)

    # Add collection to axes
    ax.add_collection(pc)

    # Plot errorbars
    artists = ax.errorbar(xdata, ydata, xerr=xerror, yerr=yerror,
                          fmt='None', ecolor='k')

    return artists

# Create figure and axes
fig, ax = plt.subplots(1)

# Call function to create error boxes
_ = make_error_boxes(ax, x, y, xerr, yerr)

plt.show()
This shows how to plot a cumulative, normalized histogram as a step function in order to visualize the empirical cumulative distribution function (CDF) of a sample. We also use the `mlab` module to show the theoretical CDF.

A couple of other options to the `hist` function are demonstrated. Namely, we use the `normed` parameter to normalize the histogram and a couple of different options to the `cumulative` parameter. The `normed` parameter takes a boolean value. When `True`, the bin heights are scaled such that the total area of the histogram is 1. The `cumulative` kwarg is a little more nuanced. Like `normed`, you can pass it True or False, but you can also pass it `-1` to reverse the distribution.

Since we’re showing a normalized and cumulative histogram, these curves are effectively the cumulative distribution functions (CDFs) of the samples. In engineering, empirical CDFs are sometimes called "non-exceedance" curves. In other words, you can look at the y-value for a given x-value to get the probability of an observation from the sample not exceeding that x-value. For example, the value of 225 on the x-axis corresponds to about 0.85 on the y-axis, so there’s an 85% chance that an observation in the sample does not exceed 225. Conversely, setting `cumulative` to `-1` as is done in the last series for this example, creates a "exceedance" curve.
Selecting different bin counts and sizes can significantly affect the shape of a histogram. The Astropy docs have a great section on how to select these parameters:

```python
import numpy as np
import matplotlib.pyplot as plt
from matplotlib import mlab

np.random.seed(0)
mu = 200
sigma = 25
n_bins = 50
x = np.random.normal(mu, sigma, size=100)

fig, ax = plt.subplots(figsize=(8, 4))

# plot the cumulative histogram
n, bins, patches = ax.hist(x, n_bins, normed=1, histtype='step',
                           cumulative=True, label='Empirical')

# Add a line showing the expected distribution.
y = mlab.normpdf(bins, mu, sigma).cumsum()
y /= y[-1]
ax.plot(bins, y, 'k--', linewidth=1.5, label='Theoretical')

# Overlay a reversed cumulative histogram.
ax.hist(x, bins=bins, normed=1, histtype='step', cumulative=-1,
        label='Reversed emp.')

# tidy up the figure
ax.grid(True)
ax.legend(loc='right')
ax.set_title('Cumulative step histograms')
ax.set_xlabel('Annual rainfall (mm)')
ax.set_ylabel('Likelihood of occurrence')

plt.show()
```

Demo of the histogram (hist) function with a few features

In addition to the basic histogram, this demo shows a few optional features:

* Setting the number of data bins
* The `normed` flag, which normalizes bin heights so that the integral of the histogram is 1. The resulting histogram is an approximation of the probability density function.
* Setting the face color of the bars
* Setting the opacity (alpha value).

Selecting different bin counts and sizes can significantly affect the shape of a histogram. The Astropy docs have a great section on how to select these parameters:

```python
import numpy as np
```
Matplotlib, Release 2.0.0

import matplotlib.mlab as mlab
import matplotlib.pyplot as plt
np.random.seed(0)
# example data
mu = 100 # mean of distribution
sigma = 15 # standard deviation of distribution
x = mu + sigma * np.random.randn(437)
num_bins = 50
fig, ax = plt.subplots()
# the histogram of the data
n, bins, patches = ax.hist(x, num_bins, normed=1)
# add a 'best fit' line
y = mlab.normpdf(bins, mu, sigma)
ax.plot(bins, y, '--')
ax.set_xlabel('Smarts')
ax.set_ylabel('Probability density')
ax.set_title(r'Histogram of IQ: $\mu=100$, $\sigma=15$')
# Tweak spacing to prevent clipping of ylabel
fig.tight_layout()
plt.show()

Demo of the histogram function's different `histtype` settings

* Histogram with step curve that has a color fill.
* Histogram with custom and unequal bin widths.

Selecting different bin counts and sizes can significantly affect the shape of a histogram. The Astropy docs have a great section on how to select these parameters: 

```python
import numpy as np
import matplotlib.pyplot as plt

np.random.seed(0)

mu = 200
sigma = 25
x = np.random.normal(mu, sigma, size=100)

fig, (ax0, ax1) = plt.subplots(ncols=2, figsize=(8, 4))

ax0.hist(x, 20, normed=1, histtype='stepfilled', facecolor='g', alpha=0.75)
ax0.set_title('stepfilled')

# Create a histogram by providing the bin edges (unequally spaced).
bins = [100, 150, 180, 195, 205, 220, 250, 300]
ax1.hist(x, bins, histtype='bar', facecolor='b')
```
import matplotlib.pyplot as plt
import numpy as np

# Create different sample sizes
x1, x2, x3 = np.random.normal(0, 1, 1000), np.random.normal(2, 3, 1000), np.random.normal(-3, 5, 1000)

fig, ax1 = plt.subplots()
ax1.hist(x1, bins=30, normed=1, histtype='bar', rwidth=0.8)
ax1.set_title('unequal bins')
fig.tight_layout()
plt.show()

Keywords: python, matplotlib, pylab, example, codex (see Search examples)

---

Demo of the histogram (hist) function with multiple data sets

Plot histogram with multiple sample sets and demonstrate:

* Use of legend with multiple sample sets
* Stacked bars
* Step curve with no fill
* Data sets of different sample sizes
Selecting different bin counts and sizes can significantly affect the shape of a histogram. The Astropy docs have a great section on how to select these parameters:

```
import numpy as np
import matplotlib.pyplot as plt

np.random.seed(0)

n_bins = 10
x = np.random.randn(1000, 3)

fig, axes = plt.subplots(nrows=2, ncols=2)
ax0, ax1, ax2, ax3 = axes.flatten()

colors = ['red', 'tan', 'lime']
ax0.hist(x, n_bins, normed=1, histtype='bar', color=colors, label=colors)
ax0.legend(prop={'size': 10})
ax0.set_title('bars with legend')

ax1.hist(x, n_bins, normed=1, histtype='bar', stacked=True)
ax1.set_title('stacked bar')

ax2.hist(x, n_bins, histtype='step', stacked=True, fill=False)
ax2.set_title('stack step (unfilled)')

# Make a multiple-histogram of data-sets with different length.
x_multi = [np.random.randn(n) for n in [10000, 5000, 2000]]
ax3.hist(x_multi, n_bins, histtype='bar')
ax3.set_title('different sample sizes')

fig.tight_layout()
plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
This example plots horizontal histograms of different samples along a categorical x-axis. Additionally, the histograms are plotted to be symmetrical about their x-position, thus making them very similar to violin plots.

To make this highly specialized plot, we can’t use the standard `hist` method. Instead we use `barh` to draw the horizontal bars directly. The vertical positions and lengths of the bars are computed via the `np.histogram` function. The histograms for all the samples are computed using the same range (min and max values) and number of bins, so that the bins for each sample are in the same vertical positions.

Selecting different bin counts and sizes can significantly affect the shape of a histogram. The Astropy docs have a great section on how to select these parameters:
import numpy as np
import matplotlib.pyplot as plt

np.random.seed(0)
number_of_bins = 20

# An example of three data sets to compare
number_of_data_points = 387
labels = ["A", "B", "C"]
data_sets = [np.random.normal(0, 1, number_of_data_points),
             np.random.normal(6, 1, number_of_data_points),
             np.random.normal(-3, 1, number_of_data_points)]

# Computed quantities to aid plotting
hist_range = (np.min(data_sets), np.max(data_sets))
binned_data_sets = [
    np.histogram(d, range=hist_range, bins=number_of_bins)[0]
    for d in data_sets
]
binned_maximums = np.max(binned_data_sets, axis=1)

# The bin_edges are the same for all of the histograms
bin_edges = np.linspace(hist_range[0], hist_range[1], number_of_bins + 1)
centers = 0.5 * (bin_edges + np.roll(bin_edges, 1))[:-1]
heights = np.diff(bin_edges)

# Cycle through and plot each histogram
fig, ax = plt.subplots()
for x_loc, binned_data in zip(x_locations, binned_data_sets):
    lefts = x_loc - 0.5 * binned_data
    ax.barh(centers, binned_data, height=heights, left=lefts)

ax.set_xticks(x_locations)
ax.set_xticklabels(labels)

ax.set_ylabel("Data values")
ax.set_xlabel("Data sets")

plt.show()
Violin Plotting Examples

Violin plots are similar to histograms and box plots in that they show an abstract representation of the probability distribution of the sample. Rather than showing counts of data points that fall into bins or order statistics, violin plots use kernel density estimation (KDE) to compute an empirical distribution of the sample. That computation is controlled by several parameters. This example demonstrates how to modify the number of points at which the KDE is evaluated (``points``) and how to modify the band-width of the KDE (``bw_method``).
For more information on violin plots and KDE, the scikit-learn docs have a great section: http://scikit-learn.org/stable/modules/density.html

```python
import random
import numpy as np
import matplotlib.pyplot as plt

# fake data
fs = 10  # fontsize
pos = [1, 2, 4, 5, 7, 8]
data = [np.random.normal(0, std, size=100) for std in pos]

fig, axes = plt.subplots(nrows=2, ncols=3, figsize=(6, 6))
axes[0, 0].violinplot(data, pos, points=20, widths=0.3,
                      showmeans=True, showextrema=True, showmedians=True)
axes[0, 0].set_title('Custom violinplot 1', fontsize=fs)
axes[0, 1].violinplot(data, pos, points=40, widths=0.5,
                      showmeans=True, showextrema=True, showmedians=True,
                      bw_method='silverman')
axes[0, 1].set_title('Custom violinplot 2', fontsize=fs)
axes[0, 2].violinplot(data, pos, points=60, widths=0.7,
                      showmeans=True, showextrema=True, showmedians=True,
                      bw_method=0.5)
axes[0, 2].set_title('Custom violinplot 3', fontsize=fs)
axes[1, 0].violinplot(data, pos, points=80, vert=False, widths=0.7,
                      showmeans=True, showextrema=True, showmedians=True)
axes[1, 0].set_title('Custom violinplot 4', fontsize=fs)
axes[1, 1].violinplot(data, pos, points=100, vert=False, widths=0.9,
                      showmeans=True, showextrema=True, showmedians=True,
                      bw_method='silverman')
axes[1, 1].set_title('Custom violinplot 5', fontsize=fs)
axes[1, 2].violinplot(data, pos, points=200, vert=False, widths=1.1,
                      showmeans=True, showextrema=True, showmedians=True,
                      bw_method=0.5)
axes[1, 2].set_title('Custom violinplot 6', fontsize=fs)

for ax in axes.flatten():
    ax.set_yticklabels([])

fig.suptitle("Violin Plotting Examples")

105.1 style_sheets example code: plot_bmh.py

```python
from numpy.random import beta
import matplotlib.pyplot as plt
plt.style.use('bmh')
```

This example demonstrates the "bmh" style, which is the design used in the Bayesian Methods for Hackers online book.
def plot_beta_hist(a, b):
    plt.hist(beta(a, b, size=10000), histtype="stepfilled",
    bins=25, alpha=0.8, normed=True)
    return

plot_beta_hist(10, 10)
plot_beta_hist(4, 12)
plot_beta_hist(50, 12)
plot_beta_hist(6, 55)

plt.show()
```python
import numpy as np
import matplotlib.pyplot as plt

plt.style.use('dark_background')

L = 6
x = np.linspace(0, L)
ncolors = len(plt.rcParams['axes.prop_cycle'])
shift = np.linspace(0, L, ncolors, endpoint=False)
for s in shift:
    plt.plot(x, np.sin(x + s), 'o-')
plt.xlabel('x-axis')
plt.ylabel('y-axis')
plt.title('title')
plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)

105.3 style_sheets example code: plot_fivethirtyeight.py
This shows an example of the "fivethirtyeight" styling, which tries to replicate the styles from FiveThirtyEight.com.

```python
from matplotlib import pyplot as plt
import numpy as np

x = np.linspace(0, 10)

with plt.style.context('fivethirtyeight'):
    plt.plot(x, np.sin(x) + x + np.random.randn(50))
    plt.plot(x, np.sin(x) + 0.5 * x + np.random.randn(50))
    plt.plot(x, np.sin(x) + 2 * x + np.random.randn(50))
    plt.plot(x, np.sin(x) - 0.5 * x + np.random.randn(50))
    plt.plot(x, np.sin(x) - 2 * x + np.random.randn(50))

plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
This example demonstrates the "ggplot" style, which adjusts the style to emulate ggplot_ (a popular plotting package for R_).

These settings were shamelessly stolen from [1]_ (with permission).

.. _ggplot: http://ggplot2.org/
.. _R: https://www.r-project.org/

import numpy as np
import matplotlib.pyplot as plt

plt.style.use('ggplot')

fig, axes = plt.subplots(nrows=2, ncols=2)
ax1, ax2, ax3, ax4 = axes.ravel()

# scatter plot (Note: plt.scatter doesn't use default colors)
x, y = np.random.normal(size=(2, 200))
```python
ax1.plot(x, y, 'o')

# sinusoidal lines with colors from default color cycle
L = 2*np.pi
x = np.linspace(0, L)
ncolors = len(plt.rcParams['axes.prop_cycle'])
shift = np.linspace(0, L, ncolors, endpoint=False)
for s in shift:
    ax2.plot(x, np.sin(x + s), '-
ax2.margins(0)

# bar graphs
x = np.arange(5)
y1, y2 = np.random.randint(1, 25, size=(2, 5))
width = 0.25
ax3.bar(x, y1, width)
ax3.bar(x + width, y2, width,
    color=list(plt.rcParams['axes.prop_cycle'])[2]['color'])
ax3.set_xticks(x + width)
ax3.set_xticklabels(['a', 'b', 'c', 'd', 'e'])

# circles with colors from default color cycle
for i, color in enumerate(plt.rcParams['axes.prop_cycle']):
    xy = np.random.normal(size=2)
    ax4.add_patch(plt.Circle(xy, radius=0.3, color=color['color']))
ax4.axis('equal')
ax4.margins(0)
plt.show()
```

Keywords: python, matplotlib, pylab, example, codex (see Search examples)
This example demonstrates the "grayscale" style sheet, which changes all colors that are defined as rc parameters to grayscale. Note, however, that not all plot elements default to colors defined by an rc parameter.

```
import numpy as np
import matplotlib.pyplot as plt

def color_cycle_example(ax):
    L = 6
    x = np.linspace(0, L)
    ncolors = len(plt.rcParams['axes.prop_cycle'])
    shift = np.linspace(0, L, ncolors, endpoint=False)
    for s in shift:
        ax.plot(x, np.sin(x + s), 'o-')

def image_and_patch_example(ax):
    ax.imshow(np.random.random(size=(20, 20)), interpolation='none')
    c = plt.Circle((5, 5), radius=5, label='patch')
```

ax.add_patch(c)

plt.style.use('grayscale')

107.1 tests example code: backend_driver.py

[source code]

```python
from __future__ import print_function, division

""
This is used to drive many of the examples across the backends, for
regression testing, and comparing backend efficiency.

You can specify the backends to be tested either via the --backends
switch, which takes a comma-separated list, or as separate arguments,
e.g.

    python backend_driver.py agg ps

would test the agg and ps backends. If no arguments are given, a
default list of backends will be tested.

Interspersed with the backend arguments can be switches for the Python
interpreter executing the tests. If entering such arguments causes an
option parsing error with the driver script, separate them from driver
switches with a --.

108.1 text_labels_and_annotations example code: autowrap_demo.py

```python
import matplotlib.pyplot as plt

fig = plt.figure()
plt.axis([0, 10, 0, 10])
t = "This is a really long string that I'd rather have wrapped so that it doesn't go outside of the figure, but if it's long enough it will go off the top or bottom!"
```

```python
"""
Auto-wrapping text demo.
"""

```
The example shows how to string together several text objects.

HISTORY
-------
On the matplotlib-users list back in February 2012, Gökhan Sever asked the
Is there a way in matplotlib to partially specify the color of a string?

Example:

```python
plt.ylabel("Today is cloudy.")
How can I show "today" as red, "is" as green and "cloudy." as blue?

Thanks.
```

Paul Ivanov responded with this answer:

```python
import matplotlib.pyplot as plt
from matplotlib import transforms

def rainbow_text(x, y, strings, colors, ax=None, **kw):
    ""
    Take a list of `strings` and `colors` and place them next to each other, with text strings[i] being shown in colors[i].

    This example shows how to do both vertical and horizontal text, and will pass all keyword arguments to plt.text, so you can set the font size, family, etc.

    The text will get added to the `ax` axes, if provided, otherwise the currently active axes will be used.
    ""

    if ax is None:
        ax = plt.gca()
    t = ax.transData
    canvas = ax.figure.canvas

    # horizontal version
    for s, c in zip(strings, colors):
        text = ax.text(x, y, s + " ", color=c, transform=t, **kw)
        text.draw(canvas.get_renderer())
        ex = text.get_window_extent()
        t = transforms.offset_copy(text._transform, x=ex.width, units='dots')

    # vertical version
    for s, c in zip(strings, colors):
        text = ax.text(x, y, s + " ", color=c, transform=t,
                        rotation=90, va='bottom', ha='center', **kw)
        text.draw(canvas.get_renderer())
        ex = text.get_window_extent()
        t = transforms.offset_copy(text._transform, y=ex.height, units='dots')

rainbow_text(0, 0, "all unicorns poop rainbows ! ! !".split(),
             ['red', 'cyan', 'brown', 'green', 'blue', 'purple', 'black'],
             size=16)
```

Demo using fontdict to control style of text and labels.

```python
import numpy as np
import matplotlib.pyplot as plt

font = {'family': 'serif',
        'color': 'darkred',
        'weight': 'normal',
        'size': 16,
       }

x = np.linspace(0.0, 5.0, 100)
```

Damped exponential decay

\[ \cos(2\pi t) \exp(-t) \]
```python
import numpy as np
dpi = 100

fig, ax = plt.subplots(figsize=(6, 6), dpi=dpi)

# example code from the matplotlib documentation

x = np.linspace(0, 10, 1000)
y = np.cos(2*np.pi*x) * np.exp(-x)

plt.plot(x, y, 'k')
plt.title('Damped exponential decay', fontdict={'family': 'serif', 'size': 16})
plt.text(2, 0.65, r'$\cos(2 \pi t) \exp(-t)$', fontdict={'family': 'serif', 'size': 16})
plt.xlabel('time (s)', fontdict={'family': 'serif', 'size': 16})
plt.ylabel('voltage (mV)', fontdict={'family': 'serif', 'size': 16})

# Tweak spacing to prevent clipping of ylabel
plt.subplots_adjust(left=0.15)
plt.show()

Keywords: python, matplotlib, pylab, example, codex (see Search examples)

### 108.4 text_labels_and_annotations example code: unicode_demo.py

```
import matplotlib.pyplot as plt

plt.title('Développés et fabriqués')
plt.xlabel('réactivité nous permettent d’être sélectionnés et adoptés')
plt.ylabel('André was here!')
plt.text(0.2, 0.8, 'Institut für Festkörperphysik', rotation=45)
plt.text(0.4, 0.2, 'AVA (check kerning)')

plt.show()
109.1 ticks_and_spines example code: spines_demo.py

Basic demo of axis spines.

This demo compares a normal axes, with spines on all four sides, and an axes
with spines only on the left and bottom.

```python
import numpy as np
import matplotlib.pyplot as plt
```

```python
def spines_demo():
    # normal spines
    fig, ax = plt.subplots()
    ax.plot([0, 1, 2, 3, 4, 5, 6], [0, 1, 2, 3, 4, 5, 6])
    ax.spines['bottom'].set_position('zero')
    ax.spines['left'].set_position('zero')
    ax.spines['right'].set_visible(False)
    ax.spines['top'].set_visible(False)
    ax.grid(True)

    # bottom-left spines
    fig, ax = plt.subplots()
    ax.plot([0, 1, 2, 3, 4, 5, 6], [0, 1, 2, 3, 4, 5, 6])
    ax.spines['bottom'].set_position('zero')
    ax.spines['left'].set_position('zero')
    ax.spines['right'].set_visible(False)
    ax.spines['top'].set_visible(False)
    ax.grid(True)

    return fig

if __name__ == '__main__':
    plt.show()
```
x = np.linspace(0, 2 * np.pi, 100)
y = 2 * np.sin(x)

fig, (ax0, ax1) = plt.subplots(nrows=2)

ax0.plot(x, y)
as0.set_title('normal spines')

```
Basic demo showing how to set tick labels to values of a series.

Using `ax.set_xticks` causes the tick labels to be set on the currently chosen ticks. However, you may want to allow matplotlib to dynamically choose the number of ticks and their spacing.

In this case it may be better to determine the tick label from the value at the tick. The following example shows how to do this.

NB: The `MaxNLocator` is used here to ensure that the tick values take integer values.

```python
import matplotlib.pyplot as plt
from matplotlib.ticker import FuncFormatter, MaxNLocator
fig = plt.figure()
ax = fig.add_subplot(111)
xs = range(26)
ys = range(26)
```
labels = list('abcdefghijklmnopqrstuvwxyz')

def format_fn(tick_val, tick_pos):
    if int(tick_val) in xs:
        return labels[int(tick_val)]
    else:
        return ''

ax.xaxis.set_major_formatter(FuncFormatter(format_fn))
at.xaxis.set_major_locator(MaxNLocator(integer=True))

ax.plot(xs, ys)
plt.show()

Keywords: python, matplotlib, pylab, example, codex (see Search examples)

109.7 ticks_and_spines example code: ticklabels_demo_rotation.py

def format_fn(tick_val, tick_pos):
    if int(tick_val) in xs:
        return labels[int(tick_val)]
    else:
        return ''

ax.xaxis.set_major_formatter(FuncFormatter(format_fn))
at.xaxis.set_major_locator(MaxNLocator(integer=True))

ax.plot(xs, ys)
plt.show()

import matplotlib.pyplot as plt

Demo of custom tick-labels with user-defined rotation.
import matplotlib.pyplot as plt

...
```python
x = [1, 2, 3, 4]
y = [1, 4, 9, 6]
labels = ['Frogs', 'Hogs', 'Bogs', 'Slogs']

plt.plot(x, y, 'ro')
# You can specify a rotation for the tick labels in degrees or with keywords.
plt.xticks(x, labels, rotation='vertical')
# Pad margins so that markers don't get clipped by the axes
plt.margins(0.2)
# Tweak spacing to prevent clipping of tick-labels
plt.subplots_adjust(bottom=0.15)
plt.show()
```

110.2 units example code: artist_tests.py
if you want to initialize them with unit data, or else they will not know how to convert the units to scalars

import random
import matplotlib.lines as lines
import matplotlib.patches as patches
import matplotlib.text as text
import matplotlib.collections as collections

from basic_units import cm, inch
import numpy as np
import matplotlib.pyplot as plt

fig, ax = plt.subplots()
ax.xaxis.set_units(cm)
ax.yaxis.set_units(cm)

if 0:
    # test a line collection
    # Not supported at present.
    verts = []
    for i in range(10):
        # a random line segment in inches
        verts.append(zip(*inch*10*np.random.rand(2, random.randint(2, 15))))
    lc = collections.LineCollection(verts, axes=ax)
    ax.add_collection(lc)

    # test a plain-ol-line
    line = lines.Line2D([0*cm, 1.5*cm], [0*cm, 2.5*cm], lw=2, color='black', axes=ax)
    ax.add_line(line)

if 0:
    # test a patch
    # Not supported at present.
    rect = patches.Rectangle((1*cm, 1*cm), width=5*cm, height=2*cm, alpha=0.2, axes=ax)
    ax.add_patch(rect)

t = text.Text(3*cm, 2.5*cm, 'text label', ha='left', va='bottom', axes=ax)
    ax.add_artist(t)

    ax.set_xlim(-1*cm, 10*cm)
    ax.set_ylim(-1*cm, 10*cm)
    #ax.xaxis.set_units(inch)
    ax.grid(True)
    ax.set_title("Artists with units")
    plt.show()
plot using a variety of cm vs inches conversions. The example shows how default unit introspection works (ax1), how various keywords can be used to set the x and y units to override the defaults (ax2, ax3, ax4) and how one can set the xlimits using scalars (ax3, current units assumed) or units (conversions applied to get the numbers to current units).

```python
import numpy as np
from basic_units import cm, inch
import matplotlib.pyplot as plt

cms = cm * np.arange(0, 10, 2)
bottom = 0*cm
width = 0.8*cm

fig = plt.figure()

ax1 = fig.add_subplot(2, 2, 1)
ax1.bar(cms, cms, bottom=bottom)
```

111.12 user_interfaces example code: embedding_in_wx3.py

[source code]
This is yet another example of using matplotlib with wx. Hopefully this is pretty full-featured:
- both matplotlib toolbar and WX buttons manipulate plot
- full wxApp framework, including widget interaction
- XRC (XML wxWidgets resource) file to create GUI (made with XRCed)

This was derived from embedding_in_wx and dynamic_image_wxagg.

Thanks to matplotlib and wx teams for creating such great software!

```python
from __future__ import print_function

import sys
import time
import os
import gc
import matplotlib
matplotlib.use('WXAgg')
import matplotlib.cm as cm
import matplotlib.cbook as cbook
from matplotlib.backends.backend_wxagg import Toolbar, FigureCanvasWxAgg
from matplotlib.figure import Figure
import numpy as np

ERR_TOL = 1e-5  # floating point slop for peak-detection

matplotlib.rc('image', origin='lower')

class PlotPanel(wx.Panel):
    def __init__(self, parent):
        wx.Panel.__init__(self, parent, -1)
        self.fig = Figure((5, 4), 75)
```

111.12. user_interfaces example code: embedding_in_wx3.py
self.canvas = FigureCanvasWxAgg(self, -1, self.fig)
self.toolbar = Toolbar(self.canvas)  # matplotlib toolbar
# self.toolbar.Realize()
# self.toolbar.set_active([0, 1])
# Now put all into a sizer
sizer = wx.BoxSizer(wx.VERTICAL)
# This way of adding to sizer allows resizing
sizer.Add(self.canvas, 1, wx.LEFT | wx.TOP | wx.GROW)
# Best to allow the toolbar to resize!
sizer.Add(self.toolbar, 0, wx.GROW)
sself.SetSizer(sizer)
sself.Fit()

def init_plot_data(self):

111.16 user_interfaces example code: fourier_demo_wx.py

[source code]
Knob - simple class with a "setKnob" method. A Knob instance is attached to a Param instance, e.g., param.attach(knob) Base class is for documentation purposes.

```python
def setKnob(self, value):
    pass

class Param(object):
    """
    The idea of the "Param" class is that some parameter in the GUI may have several knobs that both control it and reflect the parameter's state, e.g. a slider, text, and dragging can all change the value of the frequency in the waveform of this example.
    The class allows a cleaner way to update/"feedback" to the other knobs when one is being changed. Also, this class handles min/max constraints for all the knobs.
    Idea - knob list - in "set" method, knob object is passed as well - the other knobs in the knob list have a "set" method which gets called for the others.
    """

**111.28 user_interfaces example code: svg_histogram.py**

[source code]

```python
# Demonstrate how to create an interactive histogram, in which bars
# are hidden or shown by clicking on legend markers.

The interactivity is encoded in ecmascript (javascript) and inserted
in the SVG code in a post-processing step. To render the image, open it in
a web browser. SVG is supported in most web browsers used by Linux and
OSX users. Windows IE9 supports SVG, but earlier versions do not.

Notes
-----
The matplotlib backend lets us assign ids to each object. This is the
mechanism used here to relate matplotlib objects created in python and
the corresponding SVG constructs that are parsed in the second step.
While flexible, ids are cumbersome to use for large collection of
objects. Two mechanisms could be used to simplify things:
* systematic grouping of objects into SVG <g> tags,
* assigning classes to each SVG object according to its origin.

For example, instead of modifying the properties of each individual bar,
the bars from the 'hist' function could either be grouped in
a PatchCollection, or be assigned a class="hist_##" attribute.
```
CSS could also be used more extensively to replace repetitive markup throughout the generated SVG.

### 111.29 user_interfaces example code: svg_tooltip.py

[source code]

""
SVG tooltip example
====================

This example shows how to create a tooltip that will show up when hovering over a matplotlib patch.

Although it is possible to create the tooltip from CSS or javascript, here we create it in matplotlib and simply toggle its visibility on when hovering over the patch. This approach provides total control over the tooltip placement and appearance, at the expense of more code up front.

The alternative approach would be to put the tooltip content in `title` attributes of SVG objects. Then, using an existing js/CSS library, it would be relatively straightforward to create the tooltip in the browser. The content would be dictated by the `title` attribute, and the appearance by the CSS.
```python
import matplotlib.pyplot as plt
import xml.etree.ElementTree as ET
from io import BytesIO

ET.register_namespace('', 'http://www.w3.org/2000/svg')

fig, ax = plt.subplots()

# Create patches to which tooltips will be assigned.
circle = plt.Circle((0, 0), 5, fc='blue')
rect = plt.Rectangle((-5, 10), 10, 5, fc='green')

ax.add_patch(circle)
ax.add_patch(rect)

# Create the tooltips
circle_tip = ax.annotate('This is a blue circle.',
                        xy=(0, 0),
                        xytext=(30, -30),
                        textcoords='offset points',
                        color='w',
                        ha='left',
                        bbox=dict(boxstyle='round,pad=.5',
                                  fc=(.1, .1, .1, .92),
                                  ec=(1., 1., 1.),
                                  lw=1, zorder=1))

rect_tip = ax.annotate('This is a green rectangle.',
                       xy=(-5, 10),
                       xytext=(30, 40),
                       textcoords='offset points',
                       color='w',
                       ha='left',
                       bbox=dict(boxstyle='round,pad=.5',
                                 fc=(.1, .1, .1, .92),
                                 ec=(1., 1., 1.),

### 112.4 widgets example code: lasso_selector_demo.py

[source code]

```python
from __future__ import print_function
from six.moves import input
import numpy as np
from matplotlib.widgets import LassoSelector
from matplotlib.path import Path

class SelectFromCollection(object):
    """Select indices from a matplotlib collection using 'LassoSelector'.""
    Selected indices are saved in the 'ind' attribute. This tool highlights
    selected points by fading them out (i.e., reducing their alpha values).
    If your collection has alpha < 1, this tool will permanently alter them.
    
    Note that this tool selects collection objects based on their *origins*
    (i.e., 'offsets').

    Parameters
    ----------
    ax : :class:`matplotlib.axes.Axes`
        Axes to interact with.

    collection : :class:`matplotlib.collections.Collection` subclass
        Collection you want to select from.
```

```
```
alpha_other : 0 <= float <= 1
   To highlight a selection, this tool sets all selected points to an
   alpha value of 1 and non-selected points to `alpha_other`.

```python

def __init__(self, ax, collection, alpha_other=0.3):
    self.canvas = ax.figure.canvas
    self.collection = collection
    self.alpha_other = alpha_other

    self.xys = collection.get_offsets()
    self.Npts = len(self.xys)

    # Ensure that we have separate colors for each object
    self.fc = collection.get_facecolors()
    if len(self.fc) == 0:
        raise ValueError('Collection must have a facecolor')
    elif len(self.fc) == 1:

    self.lasso = LassoSelector(ax, onselect=self.onselect)
    self.ind = []

def onselect(self, verts):
    path = Path(verts)
    self.ind = np.nonzero([path.contains_point(xy) for xy in self.xys])[0]
    self.fc[:, -1] = self.alpha_other
    self.fc[self.ind, -1] = 1
    self.collection.set_facecolors(self.fc)
    self.canvas.draw_idle()

def disconnect(self):
    self.lasso.disconnect_events()
    self.fc[:, -1] = 1
    self.collection.set_facecolors(self.fc)
    self.canvas.draw_idle()

if __name__ == '__main__':
    import matplotlib.pyplot as plt

    plt.ion()
    data = np.random.rand(100, 2)

    subplot_kw = dict(xlim=(0, 1), ylim=(0, 1), autoscale_on=False)
    fig, ax = plt.subplots(subplot_kw=subplot_kw)

    pts = ax.scatter(data[:, 0], data[:, 1], s=80)
    selector = SelectFromCollection(ax, pts)

    plt.draw()
    input('Press Enter to accept selected points')
```
print("Selected points:")
print(selector.xys[selector.ind])
selector.disconnect()

# Block end of script so you can check that the lasso is disconnected.
input('Press Enter to quit')

# set useblit True on gtkagg for enhanced performance
span = SpanSelector(ax, onselect, 'horizontal', useblit=True,
rectprops=dict(alpha=0.5, facecolor='red'))

plt.show()
Part X

Glossary
AGG  The Anti-Grain Geometry (Agg) rendering engine, capable of rendering high-quality images

Cairo  The Cairo graphics engine

dateutil  The dateutil library provides extensions to the standard datetime module

EPS  Encapsulated Postscript (EPS)

FreeType  FreeType is a font rasterization library used by matplotlib which supports TrueType, Type 1, and OpenType fonts.

GDK  The Gimp Drawing Kit for GTK+

GTK  The GIMP Toolkit (GTK) graphical user interface library

JPG  The Joint Photographic Experts Group (JPEG) compression method and file format for photographic images

numpy  numpy is the standard numerical array library for python, the successor to Numeric and numarray. numpy provides fast operations for homogeneous data sets and common mathematical operations like correlations, standard deviation, fourier transforms, and convolutions.

PDF  Adobe’s Portable Document Format (PDF)

PNG  Portable Network Graphics (PNG), a raster graphics format that employs lossless data compression which is more suitable for line art than the lossy jpg format. Unlike the gif format, png is not encumbered by requirements for a patent license.

PS  Postscript (PS) is a vector graphics ASCII text language widely used in printers and publishing. Postscript was developed by adobe systems and is starting to show its age: for example is does not have an alpha channel. PDF was designed in part as a next-generation document format to replace postscript

pygtk  pygtk provides python wrappers for the GTK widgets library for use with the GTK or GTKAgg backend. Widely used on linux, and is often packages as ‘python-gtk2’

pyqt  pyqt provides python wrappers for the Qt widgets library and is required by the matplotlib Qt5Agg and Qt4Agg backends. Widely used on linux and windows; many linux distributions package this as ‘python-qt5’ or ‘python-qt4’.

python  python is an object oriented interpreted language widely used for scripting, application development, web application servers, scientific computing and more.

pytz  pytz provides the Olson tz database in Python. it allows accurate and cross platform timezone calculations and solves the issue of ambiguous times at the end of daylight savings

Qt  Qt is a cross-platform application framework for desktop and embedded development.

Qt4  Qt4 is the previous, but most widely used, version of Qt cross-platform application framework for desktop and embedded development.

Qt5  Qt5 is the current version of Qt cross-platform application framework for desktop and embedded development.

raster graphics  Raster graphics, or bitmaps, represent an image as an array of pixels which is resolution dependent. Raster graphics are generally most practical for photo-realistic images, but do not scale easily without loss of quality.
SVG  The Scalable Vector Graphics format (SVG). An XML based vector graphics format supported by many web browsers.

TIFF  Tagged Image File Format (TIFF) is a file format for storing images, including photographs and line art.

Tk   Tk is a graphical user interface for Tcl and many other dynamic languages. It can produce rich, native applications that run unchanged across Windows, Mac OS X, Linux and more.

vector graphics  vector graphics use geometrical primitives based upon mathematical equations to represent images in computer graphics. Primitives can include points, lines, curves, and shapes or polygons. Vector graphics are scalable, which means that they can be resized without suffering from issues related to inherent resolution like are seen in raster graphics. Vector graphics are generally most practical for typesetting and graphic design applications.

wxpython  wxpython provides python wrappers for the wxWidgets library for use with the WX and WX-Agg backends. Widely used on linux, OS-X and windows, it is often packaged by linux distributions as 'python-wxgtk'

wxWidgets  WX is cross-platform GUI and tools library for GTK, MS Windows, and MacOS. It uses native widgets for each operating system, so applications will have the look-and-feel that users on that operating system expect.
